                output logic y1, y2, y3, y4, y5);

   not  g1(y1, a);
   and  g2(y2, a, b);
   or   g3(y3, a, b, c);
   nand g4(y4, b, c);
   xor  g5(y5, a, c);
endmodule
```

Logic Levels

- Discrete voltages represent 1 and 0

- For example:
  - 0 = *ground* (GND) or 0 volts
  - 1 = V_{DD} or 5 volts

- What about 4.99 volts? Is that a 0 or a 1?
- What about 3.2 volts?

Logic Levels

- *Range* of voltages for 1 and 0

- Different ranges for inputs and outputs to allow for *noise*

What is Noise?

- **Anything that degrades the signal**
  - E.g., resistance, power supply noise, coupling to neighboring wires, etc.

- **Example:** a gate (driver) outputs 5 V but, because of resistance in a long wire, receiver gets 4.5 V
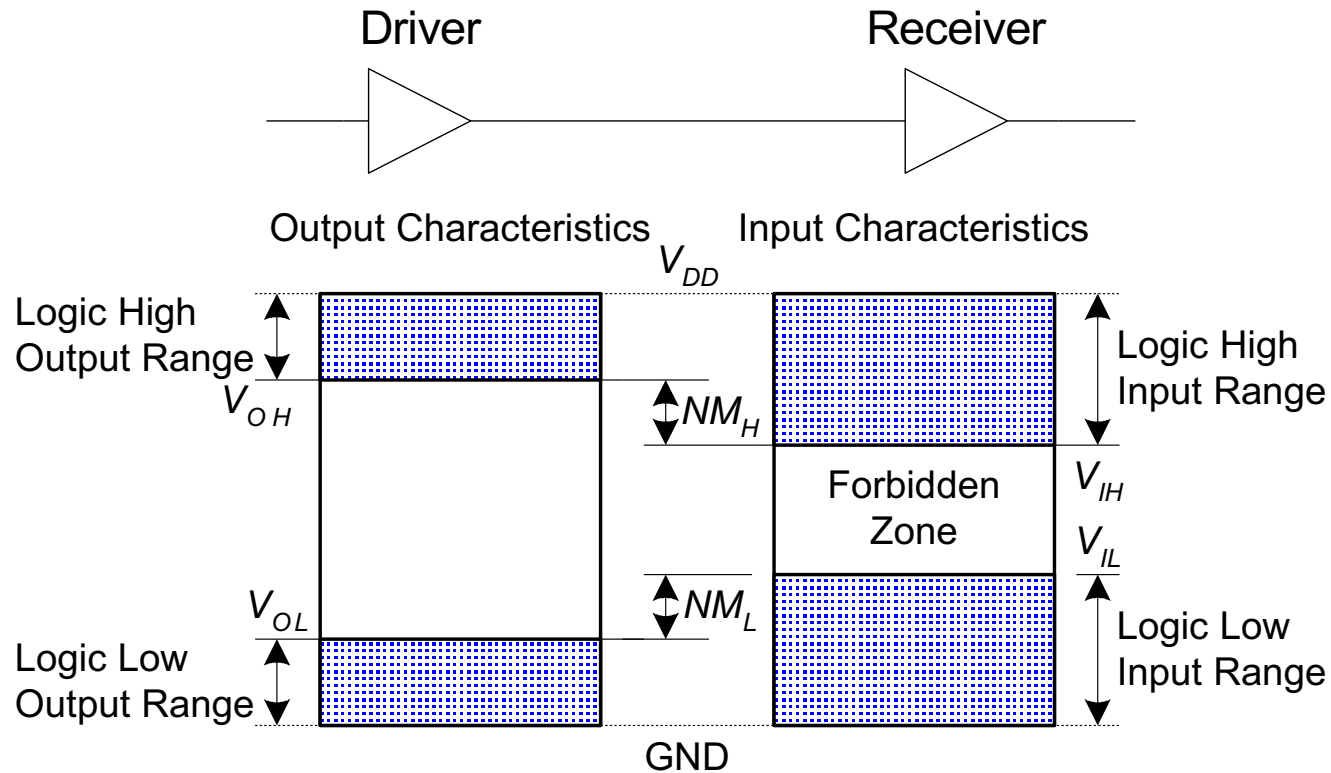

The Static Discipline

- With logically valid inputs, every circuit element must produce logically valid outputs

- Use limited ranges of voltages to represent discrete values

DC Transfer Characteristics

Ideal Buffer:

$$NM_H = NM_L = V_{DD}/2$$

Real Buffer:

Unity Gain Points Slope = 1
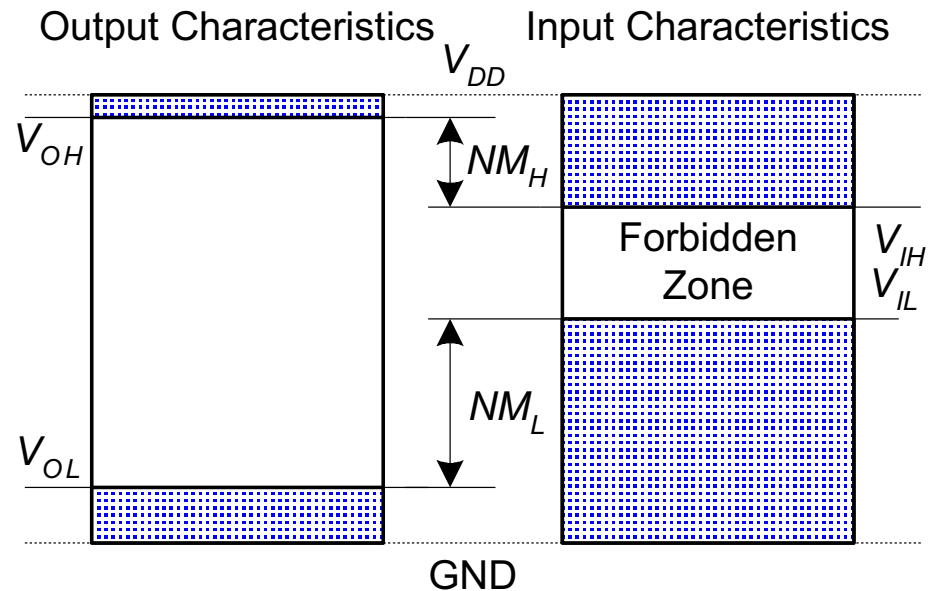

$$NM_H, NM_L < V_{DD}/2$$

DC Transfer Characteristics

V_{DD} Scaling

- In 1970's and 1980's, V_{DD} = 5 V

- V_{DD} has dropped
  - Avoid frying tiny transistors
  - Save power

- 3.3 V, 2.5 V, 1.8 V, 1.5 V, 1.2 V, 1.0 V, …
  - Be careful connecting chips with different supply voltages

V$_{DD}$ Scaling

- In 1970's and 1980's, V$_{DD}$ = 5 V
- V$_{DD}$ has dropped
  - Avoid frying tiny transistors
  - Save power
- 3.3 V, 2.5 V, 1.8 V, 1.5 V, 1.2 V, 1.0 V, …
  - Be careful connecting chips with different supply voltages

Chips operate because they contain magic smoke

Proof: if the magic smoke is let out, the chip stops working

How do you build a two-input AND gate?

Transmission Gates

- nMOS pass 1's poorly

- pMOS pass 0's poorly

- Transmission gate is a better switch
  - passes both 0 and 1 well

- When EN = 1, the switch is ON:
  - $\overline{EN}$ = 0 and A is connected to B

- When EN = 0, the switch is OFF:
  - A is not connected to B

Gordon Moore, 1929-

- Cofounded Intel in 1968 with Robert Noyce.

- **Moore's Law:** number of transistors on a computer chip doubles every year (observed in 1965)

- Since 1975, transistor counts have doubled every two years.
Moore's Law
"If the automobile had followed the same development cycle as the computer, a Rolls-Royce would today cost $100, get one million miles to the gallon, and explode once a year . . ." (Robert Cringely, Infoworld)

— Robert Cringley

Power Consumption

Power = Energy consumed per unit time

- Dynamic power consumption

- Static power consumption

Dynamic Power Consumption

- **Power to charge transistor gate capacitances**

  - Energy required to charge a capacitance, C, to V_{DD} is CV_{DD}^2

  - Circuit running at frequency f: transistors switch (from 1 to 0 or vice versa) at that frequency

  - Capacitor is charged $f/2$ times per second (discharging from 1 to 0 is free)

- **Dynamic power consumption:**

$$P_{dynamic} = \tfrac{1}{2}CV_{DD}^2f$$

Static Power Consumption

- Power consumed when no gates are switching

- Caused by the *quiescent supply current*, I_{DD} (also called the *leakage current*)

- Static power consumption:

$$P_{static} = I_{DD}V_{DD}$$

Power Consumption Example

- Estimate the power consumption of a mobile phone running Angry Birds
  - V_{DD} = 0.8 V
  - C = 5 nF
  - f = 2 GHz
  - I_{DD} = 10 mA

$$P = \tfrac{1}{2}CV_{DD}^2 f + I_{DD}V_{DD}$$

$$= \tfrac{1}{2}(5\ nF)(0.8\ V)^2(2\ GHz) + (10\ mA)(0.8\ V)$$

$$= (3.2 + 0.008)\ W \approx 3.2\ W$$

Datasheets

- **Mechanical data important when you are designing a printed circuit board.**

- **Make sure the pins fit your board!**

Example: Fanout

What is the maximum fanout for a 74LS04 NOT gate?
Solution:

    Maximum current into a 74LS04 is I_{IL} = 0.4 mA.

    Output voltage V_{OL} is guaranteed at I_{OL} = 8 mA

    Hence, maximum fanout is I_{OL} / I_{IL} = 20.

Example: Power Consumption

One 74LS04 NOT gate drives 20 identical gates. V_{CC} = 5V. What is the power consumption of the entire system if the input to the first gate switches at 1 MHz?

Static Power:

Each gate draws I_{CC} = (I_{CCL} + I_{CCH})/2 = (6.6 + 2.4 mA)/2 = 4.5 mA

I_{static} = (21 gates)(4.5 mA/gate) = 94.5 mA

P_{static} = 94.5 mA * 5 V = 472.5 mW

Dynamic Power

C_{in} is not specified. Assume 15 pF/gate * 20 gates = 300 pF.

P = $CV_{DD}2f$ = (300x10-12)(52)(1x106) = 7.5 mW

P_{total} = P_{static} + $P_{dynamic}$ = 480 mW

    TTL power is primarily static
