Review: Edge-Triggered Timing Constraints

■ Edge Triggered Flip-Flop

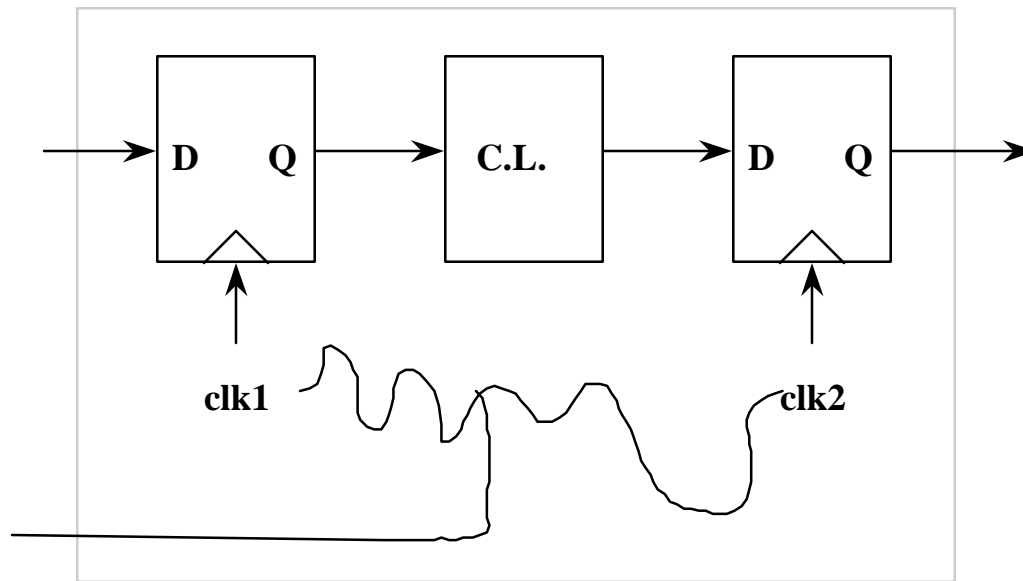

Maximum Frequency

Clock Period > $T_{pd\ c-q} + T_{pd\ cl} + T_{setup}$

Skew

$T_{hold} + T_{skew}$

<

$T_{cd\ c-q} + t_{cd\ cl}$

Clock Period >

$T_{pd\ c-q} + T_{pd\ cl} + T_{setup} + T_{skew}$

A Synchronizer as Arbiter

What Happens Now?

Flip-Flop Specification Says: Nothing

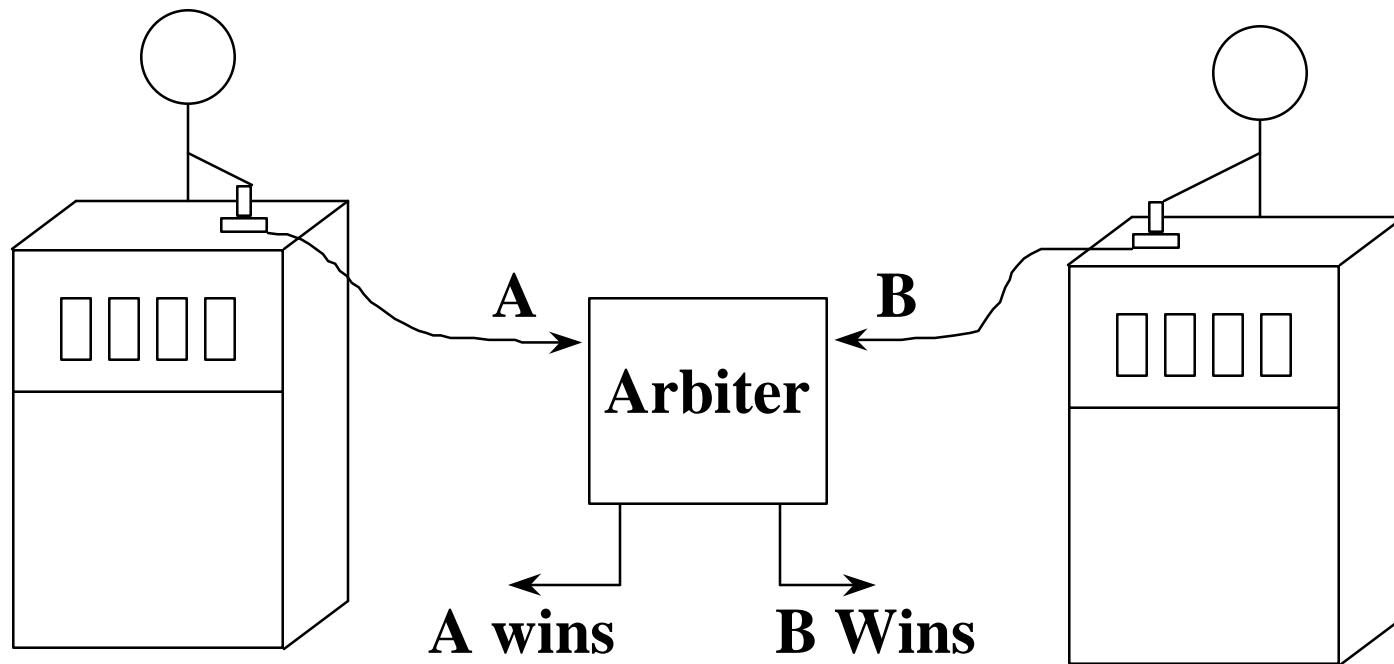

Buridan's Ass

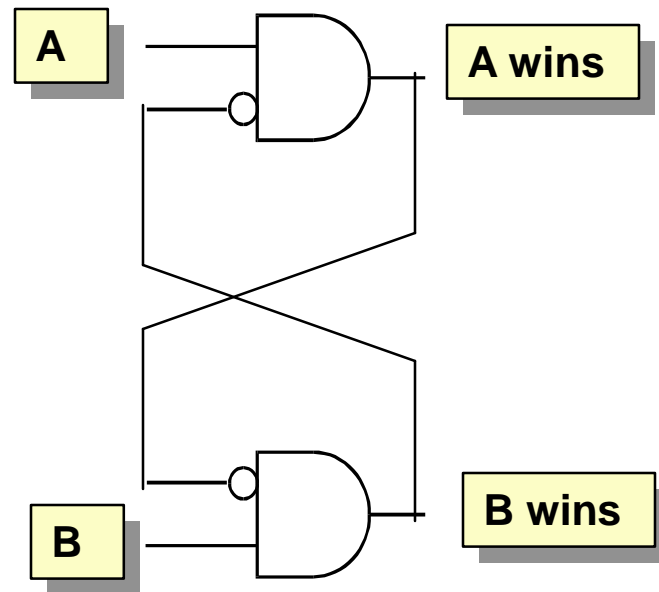

Buridan, Jean

Buridan, Jean (1300-58), French Scholastic philosopher, who held a theory of determinism, contending that the will must choose the greater good. Born in Bethune, he was educated at the University of Paris, where he studied with the English Scholastic philosopher William of Ockham. After his studies were completed, he was appointed professor of philosophy, and later rector, at the same university. Buridan is traditionally but probably incorrectly associated with a philosophical dilemma of moral choice called "Buridan's ass." In the problem an ass starves to death between two alluring bundles of hay because it does not have the will to decide which one to eat.

The Game Show Arbiter

A Simpler Arbiter

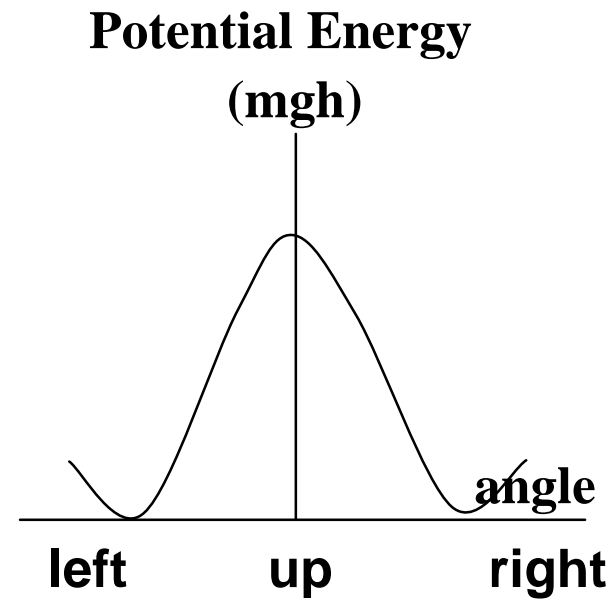

With Both Inputs High

Static Metastability

Static Metastability: Inverted Pendulum Analogy

What does Heisenberg Say ?

$$\Delta x \Delta p > h$$

What if we relax accuracy?

Who Won

**Arbiter output perfectly correct if $|T_a - T_b| > T_{margin}$
if $|T_a - T_b| \leq T_{margin}$, output can be **RANDOM****

The Remarkable Fact

The perfect arbiter:

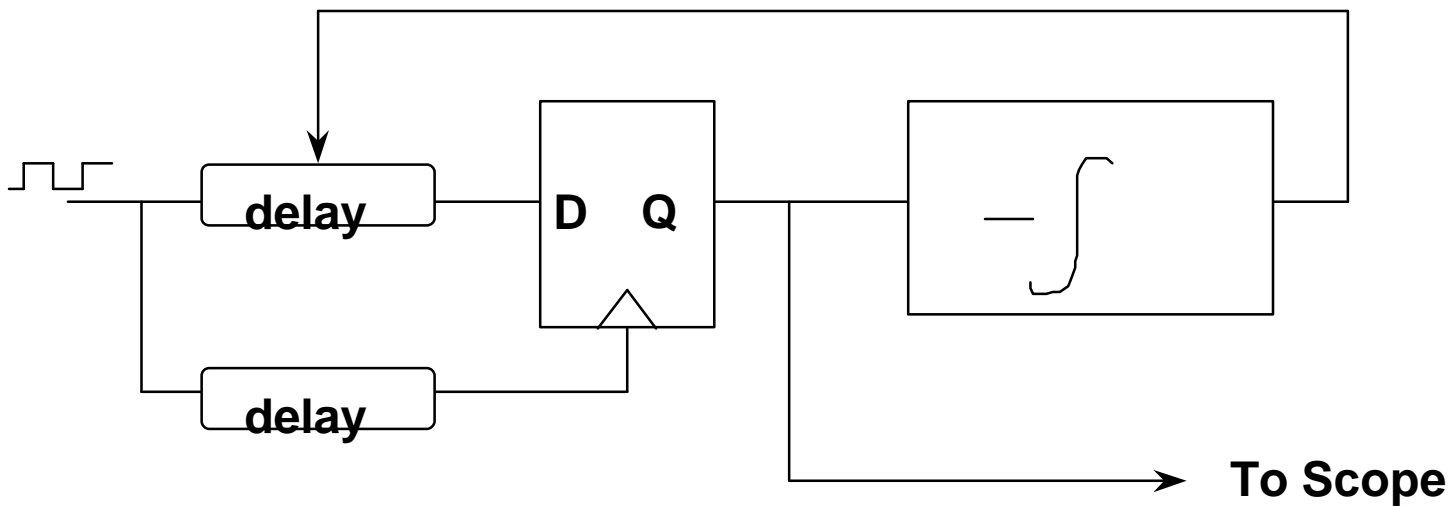

T_{margin} and T_{pd} finite and constant
Correct Output if $|T_a - T_b| > T_{margin}$
Any Output if $|T_a - T_b| \leq T_{margin}$
Answer valid and stable after T_{pd}

IT IS IMPOSSIBLE TO BUILD ! ! ! !

Dynamic Metastability (More Stupid Classroom Tricks)

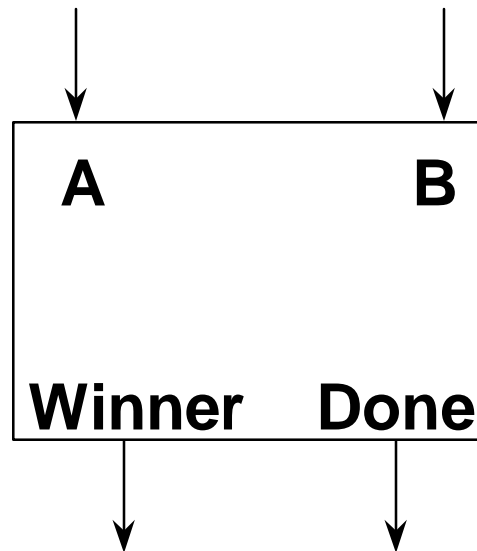

Lecture Demonstration Circuit

Is It Possible to Build This?

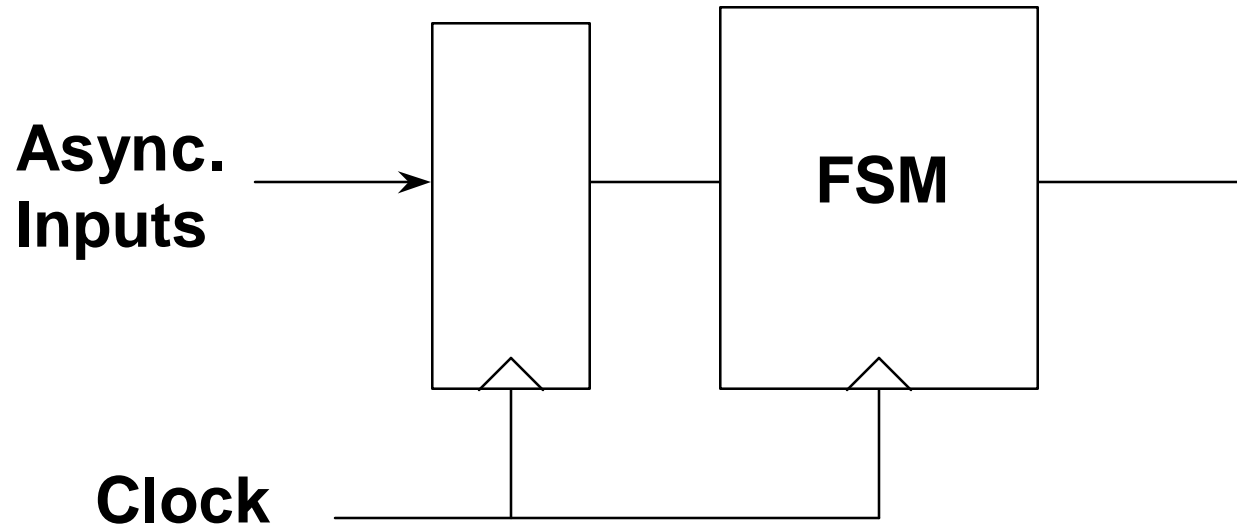

**The
Asynchronous
Arbiter:**

Answer:

Yes

Practical Metastability

A Simple Model of Static Metastability

Assume $V_{out} = A V_{in}$ (i.e. not saturated)

$$i = (A - 1) V_{in} / R$$

$$V_{in}(t) = E e^{-t(A-1)/(RC)}$$

Evolution of V_{out}

How Small must $V_{in}(0)$ be
to make time to saturation take longer
than time t ?

$$V_{in}(t) = V_{in}(0)e^{t/\tau} = \frac{1}{A}$$

$$V_{in}(0) = \frac{1}{A e^{t/\tau}} = e^{-t/\tau} / A$$

If $V_{in}(0)$ is uniformly distributed:

$$P_{\text{metastable}}(t) = \frac{1}{A e^{t/\tau}} = e^{-t/\tau} / A$$

But if V_{in} is in linear rise/fall a certain fraction ($p_{\text{transition}}$) of the time:

$$P_{\text{metastable}}(t) = \frac{p_{\text{transition}}}{A e^{t/\tau}} = (p_{\text{transition}} / A) e^{-t/\tau}$$

How much time do we need
to achieve a certain $P_{\text{metastable}}$?

$$P_{\text{metastable}}(t) = \frac{P_{\text{transition}}}{A} e^{-t/\tau}$$

$$e^{t/\tau} = \frac{P_{\text{transition}}}{A \times P_{\text{metastable}}(t)}$$

$$t = \tau \ln\left(\frac{P_{\text{transition}}}{A \times P_{\text{metastable}}(t)}\right)$$

Example:

How Long for 1 failure / year?

100 MHz Clock ($t = 10$ ns)

$$P_{\text{transition}} = 0.1$$

$$A = 10$$

$$\tau = 1 \text{ ns}$$

$$\begin{aligned} P_{\text{metstable}} &= 1 / (100\text{MHz} \cdot 1 \text{ year}) \\ &= 1 / (10^8 \times \pi \times 10^7) = \pi \times 10^{-16} \end{aligned}$$

$$P_{\text{metstable}} = \frac{P_{\text{transition}}}{A} e^{-t/\tau}$$

$$t = \tau \ln\left(\frac{P_{\text{transition}}}{A \times P_{\text{metstable}}}\right)$$

$$t = 10^{-9} \ln(0.1 / (10 \times \pi \times 10^{-16})) = \text{about } 31 \text{ ns}$$

How about 10 years instead of 1?

$$t = (10^{-9}) \ln(\pi \times 10^{-15}) = 33 \text{ ns}$$

How often will failures occur if we wait 100 ns?

$$P_{metstable}(t) = \frac{P_{transition}}{A} e^{-t/\tau}$$

$$= \frac{0.1}{10} e^{-100} = 10^{-2} \times 10^{\frac{-100}{\ln(10)}}$$

$$\approx 10^{-45.4}$$

At 100 MHz, this is about 1 failure every 10^{30} YEARS!

Age of Hominids: 10^7

Age of Earth: 10^9

Age of Universe: 10^{10}

Is this a Good Excuse For Cruising a Light?

You get 10^{30} Years!

... Later That Day ...

Honest,
Your Honor,
It Was
Metastability!

What did we Learn Today?

- If we violate setup or hold times, a flip-flop can give a random digital output.
- If we violate setup or hold times, we can't bound the propagation delay of a flip-flop.
- Metastability usually causes strange outputs, but flip-flops are sold that have valid, stable, outputs while internal nodes are metastable. They can still change their minds when coming out of metastability.
- In practice, we can choose a propagation time that will have a forever stable output “most” of the time.
- If we wait long enough (typ. 10-100 ns) “most of the time” is almost all of the time.
- We can easily detect when settling happens, but we can't say how long it will take.
