Chapter 1

About This Book

The MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set comes as part of a multi-volume set.

- Volume I-A describes conventions used throughout the document set, and provides an introduction to the MIPS32® Architecture
- Volume I-B describes conventions used throughout the document set, and provides an introduction to the microMIPS32[™] Architecture
- Volume II-A provides detailed descriptions of each instruction in the MIPS32® instruction set
- Volume II-B provides detailed descriptions of each instruction in the microMIPS32[™] instruction set
- Volume III describes the MIPS32[®] and microMIPS32[™] Privileged Resource Architecture which defines and governs the behavior of the privileged resources included in a MIPS[®] processor implementation
- Volume IV-a describes the MIPS16eTM Application-Specific Extension to the MIPS32® Architecture. Beginning with Release 3 of the Architecture, microMIPS is the preferred solution for smaller code size.
- Volume IV-b describes the MDMX[™] Application-Specific Extension to the MIPS64® Architecture and microMIPS64[™]. It is not applicable to the MIPS32® document set nor the microMIPS32[™] document set
- Volume IV-c describes the MIPS-3D® Application-Specific Extension to the MIPS® Architecture
- Volume IV-d describes the SmartMIPS®Application-Specific Extension to the MIPS32® Architecture and the microMIPS32TM Architecture
- Volume IV-e describes the MIPS® DSP Application-Specific Extension to the MIPS® Architecture
- Volume IV-f describes the MIPS® MT Application-Specific Extension to the MIPS® Architecture
- Volume IV-h describes the MIPS® MCU Application-Specific Extension to the MIPS® Architecture

1.1 Typographical Conventions

This section describes the use of *italic*, **bold** and courier fonts in this book.

1.1.1 Italic Text

• is used for *emphasis*

- is used for *bits*, *fields*, *registers*, that are important from a software perspective (for instance, address bits used by software, and programmable fields and registers), and various *floating point instruction formats*, such as *S*, *D*, and *PS*
- is used for the memory access types, such as *cached* and *uncached*

1.1.2 Bold Text

- represents a term that is being **defined**
- is used for **bits** and **fields** that are important from a hardware perspective (for instance, **register** bits, which are not programmable but accessible only to hardware)
- is used for ranges of numbers; the range is indicated by an ellipsis. For instance, **5..1** indicates numbers 5 through 1
- is used to emphasize UNPREDICTABLE and UNDEFINED behavior, as defined below.

1.1.3 Courier Text

Courier fixed-width font is used for text that is displayed on the screen, and for examples of code and instruction pseudocode.

1.2 UNPREDICTABLE and UNDEFINED

The terms **UNPREDICTABLE** and **UNDEFINED** are used throughout this book to describe the behavior of the processor in certain cases. **UNDEFINED** behavior or operations can occur only as the result of executing instructions in a privileged mode (i.e., in Kernel Mode or Debug Mode, or with the CP0 usable bit set in the Status register). Unprivileged software can never cause **UNDEFINED** behavior or operations. Conversely, both privileged and unprivileged software can cause **UNPREDICTABLE** results or operations.

1.2.1 UNPREDICTABLE

UNPREDICTABLE results may vary from processor implementation to implementation, instruction to instruction, or as a function of time on the same implementation or instruction. Software can never depend on results that are **UNPREDICTABLE**. **UNPREDICTABLE** operations may cause a result to be generated or not. If a result is generated, it is **UNPREDICTABLE**. **UNPREDICTABLE** operations may cause arbitrary exceptions.

UNPREDICTABLE results or operations have several implementation restrictions:

- Implementations of operations generating **UNPREDICTABLE** results must not depend on any data source (memory or internal state) which is inaccessible in the current processor mode
- UNPREDICTABLE operations must not read, write, or modify the contents of memory or internal state which is inaccessible in the current processor mode. For example, UNPREDICTABLE operations executed in user mode must not access memory or internal state that is only accessible in Kernel Mode or Debug Mode or in another process
- UNPREDICTABLE operations must not halt or hang the processor

1.2.2 UNDEFINED

UNDEFINED operations or behavior may vary from processor implementation to implementation, instruction to instruction, or as a function of time on the same implementation or instruction. **UNDEFINED** operations or behavior may vary from nothing to creating an environment in which execution can no longer continue. **UNDEFINED** operations or behavior may cause data loss.

UNDEFINED operations or behavior has one implementation restriction:

• **UNDEFINED** operations or behavior must not cause the processor to hang (that is, enter a state from which there is no exit other than powering down the processor). The assertion of any of the reset signals must restore the processor to an operational state

1.2.3 UNSTABLE

UNSTABLE results or values may vary as a function of time on the same implementation or instruction. Unlike **UNPREDICTABLE** values, software may depend on the fact that a sampling of an **UNSTABLE** value results in a legal transient value that was correct at some point in time prior to the sampling.

UNSTABLE values have one implementation restriction:

• Implementations of operations generating **UNSTABLE** results must not depend on any data source (memory or internal state) which is inaccessible in the current processor mode

1.3 Special Symbols in Pseudocode Notation

In this book, algorithmic descriptions of an operation are described as pseudocode in a high-level language notation resembling Pascal. Special symbols used in the pseudocode notation are listed in Table 1.1.

| Symbol | Meaning |
|-----------------|---|
| \leftarrow | Assignment |
| =, ≠ | Tests for equality and inequality |
| | Bit string concatenation |
| x ^y | A <i>y</i> -bit string formed by <i>y</i> copies of the single-bit value <i>x</i> |
| b#n | A constant value <i>n</i> in base <i>b</i> . For instance 10#100 represents the decimal value 100, 2#100 represents the binary value 100 (decimal 4), and 16#100 represents the hexadecimal value 100 (decimal 256). If the "b#" prefix is omitted, the default base is 10. |
| Obn | A constant value <i>n</i> in base 2. For instance 0b100 represents the binary value 100 (decimal 4). |
| 0xn | A constant value <i>n</i> in base 16. For instance 0x100 represents the hexadecimal value 100 (decimal 256). |
| x _{yz} | Selection of bits y through z of bit string x . Little-endian bit notation (rightmost bit is 0) is used. If y is less than z , this expression is an empty (zero length) bit string. |
| +, - | 2's complement or floating point arithmetic: addition, subtraction |
| *,× | 2's complement or floating point multiplication (both used for either) |
| div | 2's complement integer division |

Table 1.1 Symbols Used in Instruction Operation Statements

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

| Symbol | Meaning | | | |
|---------------|---|--|--|--|
| mod | 2's complement modulo | | | |
| / | Floating point division | | | |
| < | 2's complement less-than comparison | | | |
| > | 2's complement greater-than comparison | | | |
| ≤ | 2's complement less-than or equal comparison | | | |
| 2 | 2's complement greater-than or equal comparison | | | |
| nor | Bitwise logical NOR | | | |
| xor | Bitwise logical XOR | | | |
| and | Bitwise logical AND | | | |
| or | Bitwise logical OR | | | |
| GPRLEN | The length in bits (32 or 64) of the CPU general-purpose registers | | | |
| GPR[x] | CPU general-purpose register x. The content of $GPR[0]$ is always zero. In Release 2 of the Architecture, $GPR[x]$ is a short-hand notation for $SGPR[SRSCtl_{CSS}, x]$. | | | |
| SGPR[s,x] | In Release 2 of the Architecture and subsequent releases, multiple copies of the CPU general-purpose registers may be implemented. $SGPR[s,x]$ refers to GPR set <i>s</i> , register <i>x</i> . | | | |
| FPR[x] | Floating Point operand register x | | | |
| FCC[CC] | Floating Point condition code CC. FCC[0] has the same value as COC[1]. | | | |
| FPR[x] | Floating Point (Coprocessor unit 1), general register <i>x</i> | | | |
| CPR[z,x,s] | Coprocessor unit <i>z</i> , general register <i>x</i> , select <i>s</i> | | | |
| CP2CPR[x] | Coprocessor unit 2, general register x | | | |
| CCR[z,x] | Coprocessor unit <i>z</i> , control register <i>x</i> | | | |
| CP2CCR[x] | Coprocessor unit 2, control register x | | | |
| COC[z] | Coprocessor unit <i>z</i> condition signal | | | |
| Xlat[x] | Translation of the MIPS16e GPR number x into the corresponding 32-bit GPR number | | | |
| BigEndianMem | Endian mode as configured at chip reset (0 \rightarrow Little-Endian, 1 \rightarrow Big-Endian). Specifies the endianness of the memory interface (see LoadMemory and StoreMemory pseudocode function descriptions), and the endianness of Kernel and Supervisor mode execution. | | | |
| BigEndianCPU | The endianness for load and store instructions $(0 \rightarrow \text{Little-Endian}, 1 \rightarrow \text{Big-Endian})$. In User mode, this endianness may be switched by setting the <i>RE</i> bit in the <i>Status</i> register. Thus, BigEndianCPU may be computed as (BigEndianMem XOR ReverseEndian). | | | |
| ReverseEndian | Signal to reverse the endianness of load and store instructions. This feature is available in User mode only, and is implemented by setting the <i>RE</i> bit of the <i>Status</i> register. Thus, ReverseEndian may be computed as $(SR_{RE} \text{ and User mode})$. | | | |
| LLbit | Bit of virtual state used to specify operation for instructions that provide atomic read-modify-write. <i>LLbit</i> is set when a linked load occurs and is tested by the conditional store. It is cleared, during other CPU operation, when a store to the location would no longer be atomic. In particular, it is cleared by exception return instructions. | | | |

Table 1.1 Symbols Used in Instruction Operation Statements (Continued)

| Symbol | | | Meaning | |
|-----------------------------------|--|---|---|--|
| I:, I+n:, I-n: | This occurs as a prefix to <i>Operation</i> description lines and functions as a label. It indicates the instruction time during which the pseudocode appears to "execute." Unless otherwise indicated, all effects of the current instruction appear to occur during the instruction time of the current instruction. No label is equivalent to a time label of I . Sometimes effects of an instruction appear to occur either earlier or later — that is, during the instruction time of another instruction. When this happens, the instruction operation is written in sections labeled with the instruction time, relative to the current instruction I , in which the effect of that pseudocode appears to occur. For example, an instruction may have a result that is not available until after the next instruction. Such an instruction has the portion of the instruction labelled I+1 appears to occur "at the same time" as the effect of pseudocode statements labeled I for the following instruction. Within one pseudocode sequence, the effects of the statements take place in order. However, between sequences of statements for different instructions that occur "at the same time," there is no defined order. Programs must not depend on a particular order of evaluation between such sections. | | | |
| PC | The <i>Program Counter</i> value. During the instruction time of an instruction, this is the address of the instruction word. The address of the instruction that occurs during the next instruction time is determined by assigning a value to <i>PC</i> during an instruction time. If no value is assigned to <i>PC</i> during an instruction time by any pseudocode statement, it is automatically incremented by either 2 (in the case of a 16-bit MIPS16e instruction) or 4 before the next instruction time. A taken branch assigns the target address to the <i>PC</i> during the instruction time of the instruction in the branch delay slot. In the MIPS Architecture, the PC value is only visible indirectly, such as when the processor stores the restart address into a GPR on a jump-and-link or branch-and-link instruction, or into a Coprocessor 0 register on an exception. The PC value contains a full 32-bit address all of which are significant during a memory reference. | | | |
| ISA Mode | | | MIPS16e Application Specific Extension or the microMIPS base architec- it register that determines in which mode the processor is executing, as fol- | |
| | | Encoding | Meaning | |
| | | 0 | The processor is executing 32-bit MIPS instructions | |
| | | 1 | The processor is executing MIIPS16e instructions | |
| | combined value of | the upper bits o | Mode value is only visible indirectly, such as when the processor stores a of PC and the ISA Mode into a GPR on a jump-and-link or branch-and-link 0 register on an exception. | |
| PABITS | | | its implemented is represented by the symbol PABITS. As such, if 36 nented, the size of the physical address space would be $2^{\text{PABITS}} = 2^{36}$ bytes. | |
| FP32RegistersMode | has 32 32-bit FPRs | in which 64-b | bit or 64-bit floating point registers (FPRs). In MIPS32 Release 1, the FPU it data types are stored in even-odd pairs of FPRs. In MIPS64, (and option- Sr3) the FPU has 32 64-bit FPRs in which 64-bit data types are stored in | |
| | compatibility mode such a case FP32R cessor operates as i | e in which the p egisterMode i f it had 32 32-1 | tions, FP32RegistersMode is always a 0. MIPS64 implementations have a processor references the FPRs as if it were a MIPS32 implementation. In s computed from the FR bit in the <i>Status</i> register. If this bit is a 0, the probit FPRs. If this bit is a 1, the processor operates with 32 64-bit FPRs. e is computed from the FR bit in the <i>Status</i> register. | |
| InstructionInBranchDe- laySlot | or jump. This cond | ition reflects th jump occurs to | at the Program Counter address was executed in the delay slot of a branch be <i>dynamic</i> state of the instruction, not the <i>static</i> state. That is, the value is an instruction whose PC immediately follows a branch or jump, but which f a branch or jump. | |

Table 1.1 Symbols Used in Instruction Operation Statements (Continued)

| Symbol | Meaning |
|--------------------------------------|---|
| SignalException(exception, argument) | - Causes an exception to be signaled, using the exception parameter as the type of exception and the argument parameter as an exception-specific argument). Control does not return from this pseudocode function—the exception is signaled at the point of the call. |

Table 1.1 Symbols Used in Instruction Operation Statements (Continued)

Chapter 2

Guide to the Instruction Set

This chapter provides a detailed guide to understanding the instruction descriptions, which are listed in alphabetical order in the tables at the beginning of the next chapter.

2.1 Understanding the Instruction Fields

Figure 2.1 shows an example instruction. Following the figure are descriptions of the fields listed below:

- "Instruction Fields" on page 19
- "Instruction Descriptive Name and Mnemonic" on page 19
- "Format Field" on page 19
- "Purpose Field" on page 20
- "Description Field" on page 20
- "Restrictions Field" on page 20
- "Operation Field" on page 21
- "Exceptions Field" on page 21
- "Programming Notes and Implementation Notes Fields" on page 22

Figure 2.1 Example of Instruction Description

2.1.1 Instruction Fields

Fields encoding the instruction word are shown in register form at the top of the instruction description. The following rules are followed:

- The values of constant fields and the *opcode* names are listed in uppercase (SPECIAL and ADD in Figure 2.2). Constant values in a field are shown in binary below the symbolic or hexadecimal value.
- All variable fields are listed with the lowercase names used in the instruction description (*rs*, *rt*, and *rd* in Figure 2.2).
- Fields that contain zeros but are not named are unused fields that are required to be zero (bits 10:6 in Figure 2.2). If such fields are set to non-zero values, the operation of the processor is **UNPREDICTABLE**.

| 31 26 | 25 21 | 20 16 | 15 11 | 10 6 | 5 0 |
|-------------------|-------|-------|-------|------------|---------------|
| SPECIAL 000000 | rs | rt | rd | 0 00000 | ADD 100000 |
| 6 | 5 | 5 | 5 | 5 | 6 |

Figure 2.2 Example of Instruction Fields

2.1.2 Instruction Descriptive Name and Mnemonic

The instruction descriptive name and mnemonic are printed as page headings for each instruction, as shown in Figure 2.3.

Figure 2.3 Example of Instruction Descriptive Name and Mnemonic

| Add Word | ADD | |
|----------|-----|--|
|----------|-----|--|

2.1.3 Format Field

The assembler formats for the instruction and the architecture level at which the instruction was originally defined are given in the *Format* field. If the instruction definition was later extended, the architecture levels at which it was extended and the assembler formats for the extended definition are shown in their order of extension (for an example, see C.cond.fmt). The MIPS architecture levels are inclusive; higher architecture levels include all instructions in previous levels. Extensions to instructions are backwards compatible. The original assembler formats are valid for the extended architecture.

Figure 2.4 Example of Instruction Format

| Format: | ADD fd,rs,rt | MIPS32 |
|---------|--------------|--------|
| | | |

The assembler format is shown with literal parts of the assembler instruction printed in uppercase characters. The variable parts, the operands, are shown as the lowercase names of the appropriate fields. The architectural level at which the instruction was first defined, for example "MIPS32" is shown at the right side of the page.

There can be more than one assembler format for each architecture level. Floating point operations on formatted data show an assembly format with the actual assembler mnemonic for each valid value of the *fint* field. For example, the ADD.fmt instruction lists both ADD.S and ADD.D.

The assembler format lines sometimes include parenthetical comments to help explain variations in the formats (once again, see C.cond.fmt). These comments are not a part of the assembler format.

2.1.4 Purpose Field

The *Purpose* field gives a short description of the use of the instruction.

Figure 2.5 Example of Instruction Purpose

Purpose: Add Word

To add 32-bit integers. If an overflow occurs, then trap.

2.1.5 Description Field

If a one-line symbolic description of the instruction is feasible, it appears immediately to the right of the *Description* heading. The main purpose is to show how fields in the instruction are used in the arithmetic or logical operation.

| De | scription: $GPR[rd] \leftarrow GPR[rs] + GPR[rt]$ |
|-------------|--|
| The resu | e 32-bit word value in GPR <i>rt</i> is added to the 32-bit value in GPR <i>rs</i> to produce a 32-bit alt. |
| • | If the addition results in 32-bit 2's complement arithmetic overflow, the destination register is not modified and an Integer Overflow exception occurs. |
| • | If the addition does not overflow, the 32-bit result is placed into GPR rd. |
| | |

The body of the section is a description of the operation of the instruction in text, tables, and figures. This description complements the high-level language description in the *Operation* section.

This section uses acronyms for register descriptions. "GPR rt" is CPU general-purpose register specified by the instruction field rt. "FPR fs" is the floating point operand register specified by the instruction field fs. "CP1 register fd" is the coprocessor 1 general register specified by the instruction field fd. "FCSR" is the floating point Control /Status register.

2.1.6 Restrictions Field

The *Restrictions* field documents any possible restrictions that may affect the instruction. Most restrictions fall into one of the following six categories:

- Valid values for instruction fields (for example, see floating point ADD.fmt)
- ALIGNMENT requirements for memory addresses (for example, see LW)
- Valid values of operands (for example, see ALNV.PS)

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

- Valid operand formats (for example, see floating point ADD.fmt)
- Order of instructions necessary to guarantee correct execution. These ordering constraints avoid pipeline hazards for which some processors do not have hardware interlocks (for example, see MUL).
- Valid memory access types (for example, see LL/SC)

Figure 2.7 Example of Instruction Restrictions

| Restrictions: |
|---------------|
| None |
| |
| |

2.1.7 Operation Field

The *Operation* field describes the operation of the instruction as pseudocode in a high-level language notation resembling Pascal. This formal description complements the *Description* section; it is not complete in itself because many of the restrictions are either difficult to include in the pseudocode or are omitted for legibility.

Figure 2.8 Example of Instruction Operation

Operation:

```
temp ← (GPR[rs]<sub>31</sub>||GPR[rs]<sub>31..0</sub>) + (GPR[rt]<sub>31</sub>||GPR[rt]<sub>31..0</sub>)
if temp<sub>32</sub> ≠ temp<sub>31</sub> then
   SignalException(IntegerOverflow)
else
   GPR[rd] ← temp
endif
```

See 2.2 "Operation Section Notation and Functions" on page 22 for more information on the formal notation used here.

2.1.8 Exceptions Field

The *Exceptions* field lists the exceptions that can be caused by *Operation* of the instruction. It omits exceptions that can be caused by the instruction fetch, for instance, TLB Refill, and also omits exceptions that can be caused by asynchronous external events such as an Interrupt. Although a Bus Error exception may be caused by the operation of a load or store instruction, this section does not list Bus Error for load and store instructions because the relationship between load and store instructions and external error indications, like Bus Error, are dependent upon the implementation.

| Figure 2.9 Exa | ample of | Instruction | Exception |
|----------------|----------|-------------|-----------|
|----------------|----------|-------------|-----------|

| Exceptions: | |
|------------------|--|
| Integer Overflow | |

An instruction may cause implementation-dependent exceptions that are not present in the *Exceptions* section.

2.1.9 Programming Notes and Implementation Notes Fields

The *Notes* sections contain material that is useful for programmers and implementors, respectively, but that is not necessary to describe the instruction and does not belong in the description sections.

Figure 2.10 Example of Instruction Programming Notes

Programming Notes:

ADDU performs the same arithmetic operation but does not trap on overflow.

2.2 Operation Section Notation and Functions

In an instruction description, the *Operation* section uses a high-level language notation to describe the operation performed by each instruction. Special symbols used in the pseudocode are described in the previous chapter. Specific pseudocode functions are described below.

This section presents information about the following topics:

- "Instruction Execution Ordering" on page 22
- "Pseudocode Functions" on page 22

2.2.1 Instruction Execution Ordering

Each of the high-level language statements in the *Operations* section are executed sequentially (except as constrained by conditional and loop constructs).

2.2.2 Pseudocode Functions

There are several functions used in the pseudocode descriptions. These are used either to make the pseudocode more readable, to abstract implementation-specific behavior, or both. These functions are defined in this section, and include the following:

- "Coprocessor General Register Access Functions" on page 22
- "Memory Operation Functions" on page 24
- "Floating Point Functions" on page 27
- "Miscellaneous Functions" on page 30

2.2.2.1 Coprocessor General Register Access Functions

Defined coprocessors, except for CP0, have instructions to exchange words and doublewords between coprocessor general registers and the rest of the system. What a coprocessor does with a word or doubleword supplied to it and how a coprocessor supplies a word or doubleword is defined by the coprocessor itself. This behavior is abstracted into the functions described in this section.

COP_LW

The COP_LW function defines the action taken by coprocessor z when supplied with a word from memory during a load word operation. The action is coprocessor-specific. The typical action would be to store the contents of mem-word in coprocessor general register *rt*.

Figure 2.11 COP_LW Pseudocode Function

```
COP_LW (z, rt, memword)
    z: The coprocessor unit number
    rt: Coprocessor general register specifier
    memword: A 32-bit word value supplied to the coprocessor
    /* Coprocessor-dependent action */
endfunction COP_LW
```

COP_LD

The COP_LD function defines the action taken by coprocessor z when supplied with a doubleword from memory during a load doubleword operation. The action is coprocessor-specific. The typical action would be to store the contents of memdouble in coprocessor general register *rt*.

Figure 2.12 COP_LD Pseudocode Function

```
COP_LD (z, rt, memdouble)
    z: The coprocessor unit number
    rt: Coprocessor general register specifier
    memdouble: 64-bit doubleword value supplied to the coprocessor.
    /* Coprocessor-dependent action */
endfunction COP_LD
```

COP SW

The COP_SW function defines the action taken by coprocessor z to supply a word of data during a store word operation. The action is coprocessor-specific. The typical action would be to supply the contents of the low-order word in coprocessor general register rt.

Figure 2.13 COP_SW Pseudocode Function

```
dataword ← COP_SW (z, rt)
z: The coprocessor unit number
rt: Coprocessor general register specifier
dataword: 32-bit word value
/* Coprocessor-dependent action */
```

endfunction COP_SW

COP_SD

The COP_SD function defines the action taken by coprocessor *z* to supply a doubleword of data during a store doubleword operation. The action is coprocessor-specific. The typical action would be to supply the contents of the low-order doubleword in coprocessor general register *rt*.

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

Figure 2.14 COP_SD Pseudocode Function

```
datadouble ← COP_SD (z, rt)
    z: The coprocessor unit number
    rt: Coprocessor general register specifier
    datadouble: 64-bit doubleword value
    /* Coprocessor-dependent action */
endfunction COP_SD
```

CoprocessorOperation

The CoprocessorOperation function performs the specified Coprocessor operation.

Figure 2.15 CoprocessorOperation Pseudocode Function

CoprocessorOperation (z, cop_fun)

```
/* z: Coprocessor unit number */
/* cop_fun: Coprocessor function from function field of instruction */
/* Transmit the cop_fun value to coprocessor z */
endfunction CoprocessorOperation
```

2.2.2.2 Memory Operation Functions

Regardless of byte ordering (big- or little-endian), the address of a halfword, word, or doubleword is the smallest byte address of the bytes that form the object. For big-endian ordering this is the most-significant byte; for a little-endian ordering this is the least-significant byte.

In the *Operation* pseudocode for load and store operations, the following functions summarize the handling of virtual addresses and the access of physical memory. The size of the data item to be loaded or stored is passed in the *AccessLength* field. The valid constant names and values are shown in Table 2.1. The bytes within the addressed unit of memory (word for 32-bit processors or doubleword for 64-bit processors) that are used can be determined directly from the *AccessLength* and the two or three low-order bits of the address.

AddressTranslation

The AddressTranslation function translates a virtual address to a physical address and its cacheability and coherency attribute, describing the mechanism used to resolve the memory reference.

Given the virtual address *vAddr*, and whether the reference is to Instructions or Data (*IorD*), find the corresponding physical address (*pAddr*) and the cacheability and coherency attribute (*CCA*) used to resolve the reference. If the virtual address is in one of the unmapped address spaces, the physical address and *CCA* are determined directly by the virtual address. If the virtual address is in one of the mapped address spaces then the TLB or fixed mapping MMU determines the physical address and access type; if the required translation is not present in the TLB or the desired access is not permitted, the function fails and an exception is taken.

Figure 2.16 AddressTranslation Pseudocode Function

```
(pAddr, CCA) ← AddressTranslation (vAddr, IorD, LorS)
    /* pAddr: physical address */
    /* CCA: Cacheability&Coherency Attribute,the method used to access caches*/
```

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

Copyright © 2001-2003,2005,2008-2010 MIPS Technologies Inc. All rights reserved.

```
/* and memory and resolve the reference */
/* vAddr: virtual address */
/* IorD: Indicates whether access is for INSTRUCTION or DATA */
/* LorS: Indicates whether access is for LOAD or STORE */
/* See the address translation description for the appropriate MMU */
/* type in Volume III of this book for the exact translation mechanism */
```

endfunction AddressTranslation

LoadMemory

The LoadMemory function loads a value from memory.

This action uses cache and main memory as specified in both the Cacheability and Coherency Attribute (*CCA*) and the access (*IorD*) to find the contents of *AccessLength* memory bytes, starting at physical location *pAddr*. The data is returned in a fixed-width naturally aligned memory element (*MemElem*). The low-order 2 (or 3) bits of the address and the *AccessLength* indicate which of the bytes within *MemElem* need to be passed to the processor. If the memory access type of the reference is *uncached*, only the referenced bytes are read from memory and marked as valid within the memory element. If the access type is *cached* but the data is not present in cache, an implementation-specific *size* and *alignment* block of memory is read and loaded into the cache to satisfy a load reference. At a minimum, this block is the entire memory element.

Figure 2.17 LoadMemory Pseudocode Function

```
MemElem ← LoadMemory (CCA, AccessLength, pAddr, vAddr, IorD)
   /* MemElem:
                Data is returned in a fixed width with a natural alignment. The */
   /*
                width is the same size as the CPU general-purpose register, */
   /*
                32 or 64 bits, aligned on a 32- or 64-bit boundary, */
   /*
                respectively. */
   /* CCA:
                Cacheability&CoherencyAttribute=method used to access caches */
   /*
                and memory and resolve the reference */
   /* AccessLength: Length, in bytes, of access */
   /* pAddr: physical address */
   /* vAddr:
                virtual address */
   /* IorD:
                Indicates whether access is for Instructions or Data */
```

endfunction LoadMemory

StoreMemory

The StoreMemory function stores a value to memory.

The specified data is stored into the physical location *pAddr* using the memory hierarchy (data caches and main memory) as specified by the Cacheability and Coherency Attribute (*CCA*). The *MemElem* contains the data for an aligned, fixed-width memory element (a word for 32-bit processors, a doubleword for 64-bit processors), though only the bytes that are actually stored to memory need be valid. The low-order two (or three) bits of *pAddr* and the *AccessLength* field indicate which of the bytes within the *MemElem* data should be stored; only these bytes in memory will actually be changed.

Figure 2.18 StoreMemory Pseudocode Function

StoreMemory (CCA, AccessLength, MemElem, pAddr, vAddr)

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

Copyright © 2001-2003,2005,2008-2010 MIPS Technologies Inc. All rights reserved.

```
/* CCA:
          Cacheability&Coherency Attribute, the method used to access */
/* caches and memory and resolve the reference. */
/* AccessLength: Length, in bytes, of access */
/* MemElem: Data in the width and alignment of a memory element. */
/* The width is the same size as the CPU general */
/*
            purpose register, either 4 or 8 bytes, */
/*
            aligned on a 4- or 8-byte boundary. For a */
          partial-memory-element store, only the bytes that will be*/
/*
          stored must be valid.*/
/*
/* pAddr: physical address */
/* vAddr: virtual address */
```

```
endfunction StoreMemory
```

Prefetch

The Prefetch function prefetches data from memory.

Prefetch is an advisory instruction for which an implementation-specific action is taken. The action taken may increase performance but must not change the meaning of the program or alter architecturally visible state.

Figure 2.19 Prefetch Pseudocode Function

```
Prefetch (CCA, pAddr, vAddr, DATA, hint)
```

```
/* CCA: Cacheability&Coherency Attribute, the method used to access */
/* caches and memory and resolve the reference. */
/* pAddr: physical address */
/* vAddr: virtual address */
/* DATA: Indicates that access is for DATA */
/* hint: hint that indicates the possible use of the data */
```

```
endfunction Prefetch
```

Table 2.1 lists the data access lengths and their labels for loads and stores.

| AccessLength Name | Value | Meaning |
|-------------------|-------|-------------------|
| DOUBLEWORD | 7 | 8 bytes (64 bits) |
| SEPTIBYTE | 6 | 7 bytes (56 bits) |
| SEXTIBYTE | 5 | 6 bytes (48 bits) |
| QUINTIBYTE | 4 | 5 bytes (40 bits) |
| WORD | 3 | 4 bytes (32 bits) |
| TRIPLEBYTE | 2 | 3 bytes (24 bits) |
| HALFWORD | 1 | 2 bytes (16 bits) |
| BYTE | 0 | 1 byte (8 bits) |

| Table 2.1 AccessLength | Specifications | for Loads/Stores |
|------------------------|----------------|------------------|
|------------------------|----------------|------------------|

SyncOperation

The SyncOperation function orders loads and stores to synchronize shared memory.

This action makes the effects of the synchronizable loads and stores indicated by *stype* occur in the same order for all processors.

Figure 2.20 SyncOperation Pseudocode Function

SyncOperation(stype)

/* stype: Type of load/store ordering to perform. */

```
/* Perform implementation-dependent operation to complete the */
```

/* required synchronization operation */

endfunction SyncOperation

2.2.2.3 Floating Point Functions

The pseudocode shown in below specifies how the unformatted contents loaded or moved to CP1 registers are interpreted to form a formatted value. If an FPR contains a value in some format, rather than unformatted contents from a load (uninterpreted), it is valid to interpret the value in that format (but not to interpret it in a different format).

ValueFPR

The ValueFPR function returns a formatted value from the floating point registers.

Figure 2.21 ValueFPR Pseudocode Function

```
value ← ValueFPR(fpr, fmt)
   /* value: The formattted value from the FPR */
   /* fpr:
             The FPR number */
   /* fmt: The format of the data, one of: */
   /*
             S, D, W, L, PS, */
   /*
             OB, QH, */
   /*
             UNINTERPRETED_WORD, */
   /*
             UNINTERPRETED DOUBLEWORD */
   /* The UNINTERPRETED values are used to indicate that the datatype */
   /* is not known as, for example, in SWC1 and SDC1 */
   case fmt of
       S, W, UNINTERPRETED_WORD:
          valueFPR \leftarrow FPR[fpr]
      D, UNINTERPRETED_DOUBLEWORD:
          if (FP32RegistersMode = 0)
              if (fpr_0 \neq 0) then
                 valueFPR ← UNPREDICTABLE
              else
                 valueFPR \leftarrow FPR[fpr+1]<sub>31..0</sub> || FPR[fpr]<sub>31..0</sub>
              endif
          else
             valueFPR \leftarrow FPR[fpr]
          endif
      L, PS:
          if (FP32RegistersMode = 0) then
```

```
MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00
```

```
else
valueFPR ← FPR[fpr]
endif
DEFAULT:
valueFPR ← UNPREDICTABLE
endcase
endfunction ValueFPR
```

The pseudocode shown below specifies the way a binary encoding representing a formatted value is stored into CP1 registers by a computational or move operation. This binary representation is visible to store or move-from instructions. Once an FPR receives a value from the StoreFPR(), it is not valid to interpret the value with ValueFPR() in a different format.

StoreFPR

Figure 2.22 StoreFPR Pseudocode Function

```
StoreFPR (fpr, fmt, value)
   /* fpr:
              The FPR number */
   /* fmt:
              The format of the data, one of: */
   /*
              S, D, W, L, PS, */
   /*
              OB, QH, */
   /*
              UNINTERPRETED_WORD, */
   /*
              UNINTERPRETED_DOUBLEWORD */
   /* value: The formattted value to be stored into the FPR */
   /* The UNINTERPRETED values are used to indicate that the datatype ^{\star/}
   /* is not known as, for example, in LWC1 and LDC1 */
   case fmt of
       S, W, UNINTERPRETED_WORD:
           FPR[fpr] \leftarrow value
       D, UNINTERPRETED_DOUBLEWORD:
           if (FP32RegistersMode = 0)
              if (fpr_0 \neq 0) then
                  UNPREDICTABLE
              else
                  FPR[fpr] \leftarrow UNPREDICTABLE^{32} \parallel value_{31}
                  FPR[fpr+1] \leftarrow UNPREDICTABLE^{32} \parallel value_{63...32}
              endif
           else
              FPR[fpr] \leftarrow value
           endif
       L, PS:
           if (FP32RegistersMode = 0) then
              UNPREDICTABLE
           else
              FPR[fpr] \leftarrow value
           endif
```

endcase

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

endfunction StoreFPR

The pseudocode shown below checks for an enabled floating point exception and conditionally signals the exception.

CheckFPException

Figure 2.23 CheckFPException Pseudocode Function

CheckFPException()

```
/* A floating point exception is signaled if the E bit of the Cause field is a 1 */
/* (Unimplemented Operations have no enable) or if any bit in the Cause field */
/* and the corresponding bit in the Enable field are both 1 */
if ( (FCSR<sub>17</sub> = 1) or
        ((FCSR<sub>16..12</sub> and FCSR<sub>11..7</sub>) ≠ 0)) ) then
        SignalException(FloatingPointException)
endif
```

endfunction CheckFPException

FPConditionCode

The FPConditionCode function returns the value of a specific floating point condition code.

Figure 2.24 FPConditionCode Pseudocode Function

```
tf ←FPConditionCode(cc)
```

```
/* tf: The value of the specified condition code */
/* cc: The Condition code number in the range 0..7 */
if cc = 0 then
    FPConditionCode \leftarrow FCSR<sub>23</sub>
else
    FPConditionCode \leftarrow FCSR<sub>24+cc</sub>
endif
```

endfunction FPConditionCode

SetFPConditionCode

The SetFPConditionCode function writes a new value to a specific floating point condition code.

Figure 2.25 SetFPConditionCode Pseudocode Function

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

2.2.2.4 Miscellaneous Functions

This section lists miscellaneous functions not covered in previous sections.

SignalException

The SignalException function signals an exception condition.

This action results in an exception that aborts the instruction. The instruction operation pseudocode never sees a return from this function call.

Figure 2.26 SignalException Pseudocode Function

```
SignalException(Exception, argument)
```

/* Exception: The exception condition that exists. */
/* argument: A exception-dependent argument, if any */

endfunction SignalException

SignalDebugBreakpointException

The SignalDebugBreakpointException function signals a condition that causes entry into Debug Mode from non-Debug Mode.

This action results in an exception that aborts the instruction. The instruction operation pseudocode never sees a return from this function call.

Figure 2.27 SignalDebugBreakpointException Pseudocode Function

SignalDebugBreakpointException()

endfunction SignalDebugBreakpointException

SignalDebugModeBreakpointException

The SignalDebugModeBreakpointException function signals a condition that causes entry into Debug Mode from Debug Mode (i.e., an exception generated while already running in Debug Mode).

This action results in an exception that aborts the instruction. The instruction operation pseudocode never sees a return from this function call.

Figure 2.28 SignalDebugModeBreakpointException Pseudocode Function

SignalDebugModeBreakpointException()

endfunction SignalDebugModeBreakpointException

NullifyCurrentInstruction

The NullifyCurrentInstruction function nullifies the current instruction.

The instruction is aborted, inhibiting not only the functional effect of the instruction, but also inhibiting all exceptions detected during fetch, decode, or execution of the instruction in question. For branch-likely instructions, nullification kills the instruction in the delay slot of the branch likely instruction.

Figure 2.29 NullifyCurrentInstruction PseudoCode Function

```
NullifyCurrentInstruction()
```

```
endfunction NullifyCurrentInstruction
```

JumpDelaySlot

The JumpDelaySlot function is used in the pseudocode for the PC-relative instructions in the MIPS16e ASE. The function returns TRUE if the instruction at *vAddr* is executed in a jump delay slot. A jump delay slot always immediately follows a JR, JAL, JALR, or JALX instruction.

Figure 2.30 JumpDelaySlot Pseudocode Function

```
JumpDelaySlot(vAddr)
```

```
/* vAddr:Virtual address */
```

endfunction JumpDelaySlot

PolyMult

The PolyMult function multiplies two binary polynomial coefficients.

Figure 2.31 PolyMult Pseudocode Function

2.3 Op and Function Subfield Notation

In some instructions, the instruction subfields *op* and *function* can have constant 5- or 6-bit values. When reference is made to these instructions, uppercase mnemonics are used. For instance, in the floating point ADD instruction, *op*=COP1 and *function*=ADD. In other cases, a single field has both fixed and variable subfields, so the name contains both upper- and lowercase characters.

2.4 FPU Instructions

In the detailed description of each FPU instruction, all variable subfields in an instruction format (such as *fs*, *ft*, *imme*-*diate*, and so on) are shown in lowercase. The instruction name (such as ADD, SUB, and so on) is shown in upper-case.

For the sake of clarity, an alias is sometimes used for a variable subfield in the formats of specific instructions. For example, rs=base in the format for load and store instructions. Such an alias is always lowercase since it refers to a variable subfield.

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

Copyright © 2001-2003,2005,2008-2010 MIPS Technologies Inc. All rights reserved.

Bit encodings for mnemonics are given in Volume I, in the chapters describing the CPU, FPU, MDMX, and MIPS16e instructions.

See "Op and Function Subfield Notation" on page 31 for a description of the op and function subfields.

The MIPS32® Instruction Set

3.1 Compliance and Subsetting

To be compliant with the MIPS32 Architecture, designs must implement a set of required features, as described in this document set. To allow flexibility in implementations, the MIPS32 Architecture does provide subsetting rules. An implementation that follows these rules is compliant with the MIPS32 Architecture as long as it adheres strictly to the rules, and fully implements the remaining instructions. Supersetting of the MIPS32 Architecture is only allowed by adding functions to the *SPECIAL2* major opcode, by adding control for co-processors via the *COP2*, *LWC2*, *SWC2*, *LDC2*, and/or *SDC2*, or via the addition of approved Application Specific Extensions.

Note: The use of COP3 as a customizable coprocessor has been removed in the Release 2 of the MIPS32 architecture. The use of the COP3 is now reserved for the future extension of the architecture. Implementations using Release1 of the MIPS32 architecture are strongly discouraged from using the COP3 opcode for a user-available coprocessor as doing so will limit the potential for an upgrade path to a 64-bit floating point unit.

The instruction set subsetting rules are as follows:

- All CPU instructions must be implemented no subsetting is allowed (unless described in this list).
- The FPU and related support instructions, including the MOVF and MOVT CPU instructions, may be omitted. Software may determine if an FPU is implemented by checking the state of the FP bit in the *Config1* CP0 register. If the FPU is implemented, it must include S, D, and W formats, operate instructions, and all supporting instructions. Software may determine which FPU data types are implemented by checking the appropriate bit in the *FIR* CP1 register. The following allowable FPU subsets are compliant with the MIPS32 architecture:
 - No FPU
 - FPU with S, D, and W formats and all supporting instructions
- Coprocessor 2 is optional and may be omitted. Software may determine if Coprocessor 2 is implemented by checking the state of the C2 bit in the *Config1* CP0 register. If Coprocessor 2 is implemented, the Coprocessor 2 interface instructions (BC2, CFC2, COP2, CTC2, LDC2, LWC2, MFC2, MTC2, SDC2, and SWC2) may be omitted on an instruction-by-instruction basis.
- Supervisor Mode is optional. If Supervisor Mode is not implemented, bit 3 of the *Status* register must be ignored on write and read as zero.
- The standard TLB-based memory management unit may be replaced with a simpler MMU (e.g., a Fixed Mapping MMU). If this is done, the rest of the interface to the Privileged Resource Architecture must be preserved. If a TLB-based memory management unit is implemented, it must be the standard TLB-based MMU as described in the Privileged Resource Architecture chapter. Software may determine the type of the MMU by checking the MT field in the *Config* CP0 register.

- The Privileged Resource Architecture includes several implementation options and may be subsetted in accordance with those options.
- Instruction, CP0 Register, and CP1 Control Register fields that are marked "Reserved" or shown as "0" in the description of that field are reserved for future use by the architecture and are not available to implementations. Implementations may only use those fields that are explicitly reserved for implementation dependent use.
- Supported ASEs are optional and may be subsetted out. If most cases, software may determine if a supported ASE is implemented by checking the appropriate bit in the *Config1* or *Config3* CP0 register. If they are implemented, they must implement the entire ISA applicable to the component, or implement subsets that are approved by the ASE specifications.
- EJTAG is optional and may be subsetted out. If it is implemented, it must implement only those subsets that are approved by the EJTAG specification.
- The JALX instruction is only implemented when there are other instruction sets are available on the device (microMIPS or MIPS16e).
- If any instruction is subsetted out based on the rules above, an attempt to execute that instruction must cause the appropriate exception (typically Reserved Instruction or Coprocessor Unusable).

3.2 Alphabetical List of Instructions

Table 3.1 through Table 3.24 provide a list of instructions grouped by category. Individual instruction descriptions follow the tables, arranged in alphabetical order.

| Mnemonic | Instruction |
|----------|---|
| ADD | Add Word |
| ADDI | Add Immediate Word |
| ADDIU | Add Immediate Unsigned Word |
| ADDU | Add Unsigned Word |
| CLO | Count Leading Ones in Word |
| CLZ | Count Leading Zeros in Word |
| DIV | Divide Word |
| DIVU | Divide Unsigned Word |
| MADD | Multiply and Add Word to Hi, Lo |
| MADDU | Multiply and Add Unsigned Word to Hi, Lo |
| MSUB | Multiply and Subtract Word to Hi, Lo |
| MSUBU | Multiply and Subtract Unsigned Word to Hi, Lo |
| MUL | Multiply Word to GPR |
| MULT | Multiply Word |
| MULTU | Multiply Unsigned Word |

Table 3.1 CPU Arithmetic Instructions

| Mnemonic | Instruction | |
|----------|-------------------------------------|------------------------|
| SEB | Sign-Extend Byte | Release 2 & subsequent |
| SEH | Sign-Extend Halftword | Release 2 & subsequent |
| SLT | Set on Less Than | |
| SLTI | Set on Less Than Immediate | |
| SLTIU | Set on Less Than Immediate Unsigned | |
| SLTU | Set on Less Than Unsigned | |
| SUB | Subtract Word | |
| SUBU | Subtract Unsigned Word | |

Table 3.1 CPU Arithmetic Instructions (Continued)

Table 3.2 CPU Branch and Jump Instructions

| Mnemonic | Instruction | |
|----------|--|--|
| В | Unconditional Branch | |
| BAL | Branch and Link | |
| BEQ | Branch on Equal | |
| BGEZ | Branch on Greater Than or Equal to Zero | |
| BGEZAL | Branch on Greater Than or Equal to Zero and Link | |
| BGTZ | Branch on Greater Than Zero | |
| BLEZ | Branch on Less Than or Equal to Zero | |
| BLTZ | Branch on Less Than Zero | |
| BLTZAL | Branch on Less Than Zero and Link | |
| BNE | Branch on Not Equal | |
| J | Jump | |
| JAL | Jump and Link | |
| JALR | Jump and Link Register | |
| JALR.HB | Jump and Link Register with Hazard Barrier | Release 2 & subsequent |
| JALX | Jump and Link Exchange | microMIPS or MIPS16e also implemented |
| JR | Jump Register | |
| JR.HB | Jump Register with Hazard Barrier | Release 2 & subsequent |

| Mnemonic | Instruction | |
|----------|--------------------------|--------------------------|
| EHB | Execution Hazard Barrier | Release 2 & subsequent |
| NOP | No Operation | |
| PAUSE | Wait for LLBit to Clear | Release 2.1 & subsequent |
| SSNOP | Superscalar No Operation | |

Table 3.3 CPU Instruction Control Instructions

Table 3.4 CPU Load, Store, and Memory Control Instructions

| Mnemonic | Instruction | |
|----------|---|----------------------|
| LB | Load Byte | |
| LBU | Load Byte Unsigned | |
| LH | Load Halfword | |
| LHU | Load Halfword Unsigned | |
| LL | Load Linked Word | |
| LW | Load Word | |
| LWL | Load Word Left | |
| LWR | Load Word Right | |
| PREF | Prefetch | |
| SB | Store Byte | |
| SC | Store Conditional Word | |
| SH | Store Halfword | |
| SW | Store Word | |
| SWL | Store Word Left | |
| SWR | Store Word Right | |
| SYNC | Synchronize Shared Memory | |
| SYNCI | Synchronize Caches to Make Instruction Writes Effective | Release 2 & subseque |

Table 3.5 CPU Logical Instructions

| Mnemonic | Instruction |
|----------|---------------|
| AND | And |
| ANDI | And Immediate |

| Mnemonic | Instruction |
|----------|------------------------|
| LUI | Load Upper Immediate |
| NOR | Not Or |
| OR | Or |
| ORI | Or Immediate |
| XOR | Exclusive Or |
| XORI | Exclusive Or Immediate |

Table 3.5 CPU Logical Instructions (Continued)

Table 3.6 CPU Insert/Extract Instructions

| Mnemonic | Instruction | |
|----------|----------------------------------|------------------------|
| EXT | Extract Bit Field | Release 2 & subsequent |
| INS | Insert Bit Field | Release 2 & subsequent |
| WSBH | Word Swap Bytes Within Halfwords | Release 2 & subsequent |

Table 3.7 CPU Move Instructions

| Mnemonic | Instruction | |
|----------|--|------------------------|
| MFHI | Move From HI Register | |
| MFLO | Move From LO Register | |
| MOVF | Move Conditional on Floating Point False | |
| MOVN | Move Conditional on Not Zero | |
| MOVT | Move Conditional on Floating Point True | |
| MOVZ | Move Conditional on Zero | |
| MTHI | Move To HI Register | |
| MTLO | Move To LO Register | |
| RDHWR | Read Hardware Register | Release 2 & subsequent |

Table 3.8 CPU Shift Instructions

| Mnemonic | Instruction | |
|----------|----------------------------|------------------------|
| ROTR | Rotate Word Right | Release 2 & subsequent |
| ROTRV | Rotate Word Right Variable | Release 2 & subsequent |
| SLL | Shift Word Left Logical | |

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

| Mnemonic | Instruction |
|----------|--------------------------------------|
| SLLV | Shift Word Left Logical Variable |
| SRA | Shift Word Right Arithmetic |
| SRAV | Shift Word Right Arithmetic Variable |
| SRL | Shift Word Right Logical |
| SRLV | Shift Word Right Logical Variable |

Table 3.8 CPU Shift Instructions (Continued)

Table 3.9 CPU Trap Instructions

| Mnemonic | Instruction |
|----------|---|
| BREAK | Breakpoint |
| SYSCALL | System Call |
| TEQ | Trap if Equal |
| TEQI | Trap if Equal Immediate |
| TGE | Trap if Greater or Equal |
| TGEI | Trap if Greater of Equal Immediate |
| TGEIU | Trap if Greater or Equal Immediate Unsigned |
| TGEU | Trap if Greater or Equal Unsigned |
| TLT | Trap if Less Than |
| TLTI | Trap if Less Than Immediate |
| TLTIU | Trap if Less Than Immediate Unsigned |
| TLTU | Trap if Less Than Unsigned |
| TNE | Trap if Not Equal |
| TNEI | Trap if Not Equal Immediate |

Table 3.10 Obsolete¹ CPU Branch Instructions

| Mnemonic | Instruction | |
|----------|---|--|
| BEQL | Branch on Equal Likely | |
| BGEZALL | Branch on Greater Than or Equal to Zero and Link Likely | |
| BGEZL | Branch on Greater Than or Equal to Zero Likely | |
| BGTZL | Branch on Greater Than Zero Likely | |
| BLEZL | Branch on Less Than or Equal to Zero Likely | |

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

| Mnemonic | Instruction |
|----------|--|
| BLTZALL | Branch on Less Than Zero and Link Likely |
| BLTZL | Branch on Less Than Zero Likely |
| BNEL | Branch on Not Equal Likely |

Table 3.10 Obsolete¹ CPU Branch Instructions (Continued)

1. Software is strongly encouraged to avoid use of the Branch Likely instructions, as they will be removed from a future revision of the MIPS32 architecture.

| Mnemonic | Instruction |
|-----------|---|
| ABS.fmt | Floating Point Absolute Value |
| ADD.fmt | Floating Point Add |
| DIV.fmt | Floating Point Divide |
| MADD.fmt | Floating Point Multiply Add |
| MSUB.fmt | Floating Point Multiply Subtract |
| MUL.fmt | Floating Point Multiply |
| NEG.fmt | Floating Point Negate |
| NMADD.fmt | Floating Point Negative Multiply Add |
| NMSUB.fmt | Floating Point Negative Multiply Subtract |
| RECIP.fmt | Reciprocal Approximation |
| RSQRT.fmt | Reciprocal Square Root Approximation |
| SQRT.fmt | Floating Point Square Root |
| SUB.fmt | Floating Point Subtract |

Table 3.11 FPU Arithmetic Instructions

Table 3.12 FPU Branch Instructions

| Mnemonic | Instruction | |
|----------|--------------------|--|
| BC1F | Branch on FP False | |
| BC1T | Branch on FP True | |

Table 3.13 FPU Compare Instructions

| Mnemonic | Instruction | |
|------------|------------------------|--|
| C.cond.fmt | Floating Point Compare | |

| Mnemonic | Instruction | |
|-------------|--|-----------------|
| ALNV.PS | Floating Point Align Variable | 64-bit FPU Only |
| CEIL.L.fmt | Floating Point Ceiling Convert to Long Fixed Point | 64-bit FPU Only |
| CEIL.W.fmt | Floating Point Ceiling Convert to Word Fixed Point | |
| CVT.D.fmt | Floating Point Convert to Double Floating Point | |
| CVT.L.fmt | Floating Point Convert to Long Fixed Point | 64-bit FPU Only |
| CVT.PS.S | Floating Point Convert Pair to Paired Single | 64-bit FPU Only |
| CVT.S.PL | Floating Point Convert Pair Lower to Single Floating Point | 64-bit FPU Only |
| CVT.S.PU | Floating Point Convert Pair Upper to Single Floating Point | 64-bit FPU Only |
| CVT.S.fmt | Floating Point Convert to Single Floating Point | |
| CVT.W.fmt | Floating Point Convert to Word Fixed Point | |
| FLOOR.L.fmt | Floating Point Floor Convert to Long Fixed Point | 64-bit FPU Only |
| FLOOR.W.fmt | Floating Point Floor Convert to Word Fixed Point | |
| PLL.PS | Pair Lower Lower | 64-bit FPU Only |
| PLU.PS | Pair Lower Upper | 64-bit FPU Only |
| PUL.PS | Pair Upper Lower | 64-bit FPU Only |
| PUU.PS | Pair Upper Upper | 64-bit FPU Only |
| ROUND.L.fmt | Floating Point Round to Long Fixed Point | 64-bit FPU Only |
| ROUND.W.fmt | Floating Point Round to Word Fixed Point | |
| TRUNC.L.fmt | Floating Point Truncate to Long Fixed Point | 64-bit FPU Only |
| TRUNC.W.fmt | Floating Point Truncate to Word Fixed Point | |

Table 3.14 FPU Convert Instructions

Table 3.15 FPU Load, Store, and Memory Control Instructions

| Mnemonic | Instruction | |
|----------|---|-----------------|
| LDC1 | Load Doubleword to Floating Point | |
| LDXC1 | Load Doubleword Indexed to Floating Point | 64-bit FPU Only |
| LUXC1 | Load Doubleword Indexed Unaligned to Floating Point | 64-bit FPU Only |
| LWC1 | Load Word to Floating Point | |
| LWXC1 | Load Word Indexed to Floating Point | 64-bit FPU Only |
| PREFX | Prefetch Indexed | |
| SDC1 | Store Doubleword from Floating Point | |

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

| Mnemonic | Instruction | |
|----------|--|-----------------|
| SDXC1 | Store Doubleword Indexed from Floating Point | 64-bit FPU Only |
| SUXC1 | Store Doubleword Indexed Unaligned from Floating Point | 64-bit FPU Only |
| SWC1 | Store Word from Floating Point | |
| SWXC1 | Store Word Indexed from Floating Point | 64-bit FPU Only |

Table 3.15 FPU Load, Store, and Memory Control Instructions (Continued)

Table 3.16 FPU Move Instructions

| Mnemonic | Instruction | |
|----------|---|------------------------|
| CFC1 | Move Control Word from Floating Point | |
| CTC1 | Move Control Word to Floating Point | |
| MFC1 | Move Word from Floating Point | |
| MFHC1 | Move Word from High Half of Floating Point Register | Release 2 & subsequent |
| MOV.fmt | Floating Point Move | |
| MOVF.fmt | Floating Point Move Conditional on Floating Point False | |
| MOVN.fmt | Floating Point Move Conditional on Not Zero | |
| MOVT.fmt | Floating Point Move Conditional on Floating Point True | |
| MOVZ.fmt | Floating Point Move Conditional on Zero | |
| MTC1 | Move Word to Floating Point | |
| MTHC1 | Move Word to High Half of Floating Point Register | Release 2 & subsequent |

Table 3.17 Obsolete¹ FPU Branch Instructions

| Mnemonic | Instruction |
|----------|---------------------------|
| BC1FL | Branch on FP False Likely |
| BC1TL | Branch on FP True Likely |

1. Software is strongly encouraged to avoid use of the Branch Likely instructions, as they will be removed from a future revision of the MIPS32 architecture.

| Mnemonic | Instruction |
|----------|----------------------|
| BC2F | Branch on COP2 False |
| BC2T | Branch on COP2 True |

1. Software is strongly encouraged to avoid use of the Branch Likely instructions, as they will be removed from a future revision of the MIPS32 architecture.

Table 3.23 Privileged Instructions

| Mnemonic | Instruction |
|----------|-------------------------|
| CACHE | Perform Cache Operation |

| Mnemonic | Instruction | |
|----------|-----------------------------------|------------------------|
| DI | Disable Interrupts | Release 2 & subsequent |
| EI | Enable Interrupts | Release 2 & subsequent |
| ERET | Exception Return | |
| MFC0 | Move from Coprocessor 0 | |
| MTC0 | Move to Coprocessor 0 | |
| RDPGPR | Read GPR from Previous Shadow Set | Release 2 & subsequent |
| TLBP | Probe TLB for Matching Entry | |
| TLBR | Read Indexed TLB Entry | |
| TLBWI | Write Indexed TLB Entry | |
| TLBWR | Write Random TLB Entry | |
| WAIT | Enter Standby Mode | |
| WRPGPR | Write GPR to Previous Shadow Set | Release 2 & subsequent |

Table 3.23 Privileged Instructions (Continued)

Table 3.24 EJTAG Instructions

| Mnemonic | Instruction |
|----------|---------------------------|
| DERET | Debug Exception Return |
| SDBBP | Software Debug Breakpoint |

| 31 | | 26 | 25 | 21 | 20 | 16 | 15 | 11 | 10 | 6 | 5 | 0 |
|----|----------------|-------|------------------------------------|----|---------|----|----|----|----|---|----------------|---------------------------------|
| | COP1 010001 | - | fmt | | 0 00000 | | fs | | fd | | ABS 000101 | |
| | 6 | | 5 | | 5 | | 5 | | 5 | | 6 | |
| Fo | rmat: | ABS.D | mt fd, fs fd, fs S fd, fs | | | | | | | | MIPS64, MIPS32 | MIPS32 MIPS32 2 Release 2 |

Purpose: Floating Point Absolute Value

Description: FPR[fd] ← abs(FPR[fs])

The absolute value of the value in FPR *fs* is placed in FPR *fd*. The operand and result are values in format *fmt*. ABS.PS takes the absolute value of the two values in FPR *fs* independently, and ORs together any generated exceptions.

Cause bits are ORed into the *Flag* bits if no exception is taken.

This operation is arithmetic; a NaN operand signals invalid operation.

Restrictions:

The fields *fs* and *fd*must specify FPRs valid for operands of type *fmt*. If they are not valid, the result is **UNPREDICT-ABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of ABS.PS is **UNPREDICTABLE** if the processor is executing in 16 FP registers mode.

Operation:

```
StoreFPR(fd, fmt, AbsoluteValue(ValueFPR(fs, fmt)))
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Unimplemented Operation, Invalid Operation

| 31 | 26 | 25 | 21 | 20 | 16 | 15 | 11 | 1 | 10 | 6 | 5 | 0 |
|-------------------|----|----|----|----|----|----|----|---|------------|---|---------------|---|
| SPECIAL 000000 | | rs | | rt | | r | ď | | 0 00000 | | ADD 100000 | |
| 6 | | 5 | | 5 | | : | 5 | | 5 | | 6 | |

Format: ADD rd, rs, rt

Purpose: Add Word

To add 32-bit integers. If an overflow occurs, then trap.

Description: GPR[rd] ← GPR[rs] + GPR[rt]

The 32-bit word value in GPR rt is added to the 32-bit value in GPR rs to produce a 32-bit result.

- If the addition results in 32-bit 2's complement arithmetic overflow, the destination register is not modified and an Integer Overflow exception occurs.
- If the addition does not overflow, the 32-bit result is placed into GPR rd.

Restrictions:

None

Operation:

```
temp ← (GPR[rs]<sub>31</sub>||GPR[rs]<sub>31..0</sub>) + (GPR[rt]<sub>31</sub>||GPR[rt]<sub>31..0</sub>)
if temp<sub>32</sub> ≠ temp<sub>31</sub> then
   SignalException(IntegerOverflow)
else
   GPR[rd] ← temp
endif
```

Exceptions:

Integer Overflow

Programming Notes:

ADDU performs the same arithmetic operation but does not trap on overflow.

| 31 | 26 | 25 2 | 1 20 16 | 6 15 11 | 10 6 | 6 5 0 | |
|-------------|-------|---------------|---------|---------|------|----------------------|-------|
| COP 0100 | | fmt | ft | fs | fd | ADD 000000 | |
| 6 | | 5 | 5 | 5 | 5 | 6 | |
| Format: | ADD.f | imt | | | | | |
| | ADD.S | 5 fd, fs, ft | | | | | PS32 |
| | ADD.D |) fd, fs, ft | | | | MII | PS32 |
| | ADD.F | PS fd, fs, ft | | | | MIPS64, MIPS32 Relea | ase 2 |

Purpose: Floating Point Add

To add floating point values

Description: FPR[fd] ← FPR[fs] + FPR[ft]

The value in FPR ft is added to the value in FPR fs. The result is calculated to infinite precision, rounded by using to the current rounding mode in *FCSR*, and placed into FPR fd. The operands and result are values in format *fmt*. ADD.PS adds the upper and lower halves of FPR fs and FPR ft independently, and ORs together any generated exceptions.

Cause bits are ORed into the Flag bits if no exception is taken.

Restrictions:

The fields *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *fmt*. If they are not valid, the result is **UNPRE-DICTABLE**.

The operands must be values in format *fmt*; if they are not, the result is **UNPREDICTABLE** and the value of the operand FPRs becomes **UNPREDICTABLE**.

The result of ADD.PS is **UNPREDICTABLE** if the processor is executing in 16 FP registers mode.

Operation:

StoreFPR (fd, fmt, ValueFPR(fs, fmt) +_{fmt} ValueFPR(ft, fmt))

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Unimplemented Operation, Invalid Operation, Inexact, Overflow, Underflow

| 31 | 26 | 25 21 | 20 16 | 15 0 |
|--------|---------------|-------|-------|-----------|
| 4 0 | ADDI 01000 | rs | rt | immediate |
| | 6 | 5 | 5 | 16 |

Format: ADDI rt, rs, immediate

Purpose: Add Immediate Word

To add a constant to a 32-bit integer. If overflow occurs, then trap.

Description: GPR[rt] ← GPR[rs] + immediate

The 16-bit signed *immediate* is added to the 32-bit value in GPR rs to produce a 32-bit result.

- If the addition results in 32-bit 2's complement arithmetic overflow, the destination register is not modified and an Integer Overflow exception occurs.
- If the addition does not overflow, the 32-bit result is placed into GPR rt.

Restrictions:

None

Operation:

```
temp ← (GPR[rs]<sub>31</sub>||GPR[rs]<sub>31..0</sub>) + sign_extend(immediate)
if temp<sub>32</sub> ≠ temp<sub>31</sub> then
   SignalException(IntegerOverflow)
else
   GPR[rt] ← temp
endif
```

Exceptions:

Integer Overflow

Programming Notes:

ADDIU performs the same arithmetic operation but does not trap on overflow.

| 31 | | 26 | 25 2 | 1 20 | 16 | 15 | 0 |
|----|-----------------|-----|---------------|--------|----|-----------|--------|
| | ADDIU 001001 | | rs | rt | | immediate | |
| | 6 | | 5 | 5 | | 16 | |
| | Format: A | DDI | J rt, rs, imm | ediate | | | MIPS32 |

Format: ADDIU rt, rs, immediate

Purpose: Add Immediate Unsigned Word

To add a constant to a 32-bit integer

Description: GPR[rt] ← GPR[rs] + immediate

The 16-bit signed immediate is added to the 32-bit value in GPR rs and the 32-bit arithmetic result is placed into GPR rt.

No Integer Overflow exception occurs under any circumstances.

Restrictions:

None

Operation:

temp ← GPR[rs] + sign_extend(immediate) $GPR[rt] \leftarrow temp$

Exceptions:

None

Programming Notes:

The term "unsigned" in the instruction name is a misnomer; this operation is 32-bit modulo arithmetic that does not trap on overflow. This instruction is appropriate for unsigned arithmetic, such as address arithmetic, or integer arithmetic environments that ignore overflow, such as C language arithmetic.

Format: ADDU rd, rs, rt

Purpose: Add Unsigned Word

To add 32-bit integers

Description: GPR[rd] ← GPR[rs] + GPR[rt]

The 32-bit word value in GPR *rt* is added to the 32-bit value in GPR *rs* and the 32-bit arithmetic result is placed into GPR *rd*.

No Integer Overflow exception occurs under any circumstances.

Restrictions:

None

Operation:

temp \leftarrow GPR[rs] + GPR[rt] GPR[rd] \leftarrow temp

Exceptions:

None

Programming Notes:

The term "unsigned" in the instruction name is a misnomer; this operation is 32-bit modulo arithmetic that does not trap on overflow. This instruction is appropriate for unsigned arithmetic, such as address arithmetic, or integer arithmetic environments that ignore overflow, such as C language arithmetic.

ADDU

| 31 | 26 | 25 21 | 20 16 | 15 11 | 10 6 | 5 0 |
|----|-----------------|-------|-------|-------|------|-------------------|
| | COP1X 010011 | rs | ft | fs | fd | ALNV.PS 011110 |
| | 6 | 5 | 5 | 5 | 5 | 6 |

Format: ALNV.PS fd, fs, ft, rs

Purpose: Floating Point Align Variable

To align a misaligned pair of paired single values

Description: FPR[fd] ← ByteAlign(GPR[rs]_{2..0}, FPR[fs], FPR[ft])

FPR *fs* is concatenated with FPR *ft* and this value is funnel-shifted by GPR $rs_{2..0}$ bytes, and written into FPR *fd*. If GPR $rs_{2..0}$ is 0, FPR *fd* receives FPR *fs*. If GPR $rs_{2..0}$ is 4, the operation depends on the current endianness.

Figure 3-1 illustrates the following example: for a big-endian operation and a byte alignment of 4, the upper half of FPR *fd* receives the lower half of the paired single value in *fs*, and the lower half of FPR *fd* receives the upper half of the paired single value in FPR *ft*.

Figure 3.1 Example of an ALNV.PS Operation

The move is non arithmetic; it causes no IEEE 754 exceptions.

Restrictions:

The fields *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *PS*. If they are not valid, the result is **UNPRE-DICTABLE**.

If GPR *rs*_{1.0} are non-zero, the results are **UNPREDICTABLE**.

The result of this instruction is **UNPREDICTABLE** if the processor is executing in 16 FP registers mode.

Operation:

```
if GPR[rs]<sub>2..0</sub> = 0 then
    StoreFPR(fd, PS,ValueFPR(fs,PS))
else if GPR[rs]<sub>2..0</sub> ≠ 4 then
    UNPREDICTABLE
else if BigEndianCPU then
    StoreFPR(fd, PS, ValueFPR(fs, PS)<sub>31..0</sub> || ValueFPR(ft,PS)<sub>63..32</sub>)
else
    StoreFPR(fd, PS, ValueFPR(ft, PS)<sub>31..0</sub> || ValueFPR(fs,PS)<sub>63..32</sub>)
endif
```

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

MIPS64, MIPS32 Release 2

Exceptions:

Coprocessor Unusable, Reserved Instruction

Programming Notes:

ALNV.PS is designed to be used with LUXC1 to load 8 bytes of data from any 4-byte boundary. For example:

```
/* Copy T2 bytes (a multiple of 16) of data T0 to T1, T0 unaligned, T1 aligned.
            Reads one dw beyond the end of T0. */
   LUXC1
            F0, 0(T0) /* set up by reading 1st src dw */
           T3, 0 /* index into src and dst arrays */
   LI
   ADDIU T4, T0, 8 /* base for odd dw loads */
   ADDIU T5, T1, -8/* base for odd dw stores */
LOOP:
  LUXC1 F1, T3(T4)
   ALNV.PS F2, F0, F1, T0/* switch F0, F1 for little-endian */
   SDC1
         F2, T3(T1)
           тз, тз, 16
   ADDIU
  LUXC1
          F0, T3(T0)
   ALNV.PS F2, F1, F0, T0/* switch F1, F0 for little-endian */
   BNE T3, T2, LOOP
   SDC1
           F2, T3(T5)
DONE:
```

ALNV.PS is also useful with SUXC1 to store paired-single results in a vector loop to a possibly misaligned address:

```
/* T1[i] = T0[i] + F8, T0 aligned, T1 unaligned. */
      CVT.PS.S F8, F8, F8/* make addend paired-single */
/* Loop header computes 1st pair into F0, stores high half if T1 */
/* misaligned */
LOOP:
  LDC1
           F2, T3(T4)/* get T0[i+2]/T0[i+3] */
   ADD.PS F1, F2, F8/* compute T1[i+2]/T1[i+3] */
   ALNV.PS F3, F0, F1, T1/* align to dst memory */
   SUXC1 F3, T3(T1)/* store to T1[i+0]/T1[i+1] */
   ADDIU
           T3, 16 /* i = i + 4 */
           F2, T3(T0)/* get T0[i+0]/T0[i+1] */
  LDC1
  ADD.PS F0, F2, F8/* compute T1[i+0]/T1[i+1] */
  ALNV.PS F3, F1, F0, T1/* align to dst memory */
   BNE
           T3, T2, LOOP
   SUXC1
           F3, T3(T5)/* store to T1[i+2]/T1[i+3] */
```

/* Loop trailer stores all or half of F0, depending on T1 alignment */

| | 6 | 5 | 5 | 16 |

Format: B offset

Assembly Idiom

Purpose: Unconditional Branch

To do an unconditional branch

Description: branch

B offset is the assembly idiom used to denote an unconditional branch. The actual instruction is interpreted by the hardware as BEQ r0, r0, offset.

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

Restrictions:

Processor operation is **UNPREDICTABLE** if a branch, jump, ERET, DERET, or WAIT instruction is placed in the delay slot of a branch or jump.

Operation:

```
I: target_offset \leftarrow sign_extend(offset || 0^2)

I+1: PC \leftarrow PC + target_offset
```

Exceptions:

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is \pm 128 Kbytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

| | REGIMM 000001 | 0 00000 | BGEZAL 10001 | offset | |
| | 6 | 5 | 5 | 16 | |

Format: BAL offset

Assembly Idiom

55

Purpose: Branch and Link

To do an unconditional PC-relative procedure call

Description: procedure_call

BAL offset is the assembly idiom used to denote an unconditional branch. The actual instruction is interpreted by the hardware as BGEZAL r0, offset.

Place the return address link in GPR 31. The return link is the address of the second instruction following the branch, where execution continues after a procedure call.

An 18-bit signed offset (the 16-bit *offset* field shifted left 2bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

Restrictions:

Processor operation is **UNPREDICTABLE** if a branch, jump, ERET, DERET, or WAIT instruction is placed in the delay slot of a branch or jump.

GPR 31 must not be used for the source register *rs*, because such an instruction does not have the same effect when re-executed. The result of executing such an instruction is **UNPREDICTABLE**. This restriction permits an exception handler to resume execution by re-executing the branch when an exception occurs in the branch delay slot.

Operation:

Exceptions:

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is \pm 128 KBytes. Use jump and link (JAL) or jump and link register (JALR) instructions for procedure calls to addresses outside this range.

| 31 | 26 | 25 21 | 20 18 | 17 | 16 | 15 | 0 |
|----|----------------------|----------------------------|----------|---------|---------|--------|------------------|
| | COP1 010001 | BC 01000 | сс | nd 0 | tf 0 | offset | |
| | 6 | 5 | 3 | 1 | 1 | 16 | |
| | Format: BC1F BC1F | offset (cc = cc, offset | 0 implie | d) | | | MIPS32 MIPS32 |

Purpose: Branch on FP False

To test an FP condition code and do a PC-relative conditional branch

Description: if FPConditionCode(cc) = 0 then branch

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself) in the branch delay slot to form a PC-relative effective target address. If the FP condition code bit *cc* is false (0), the program branches to the effective target address after the instruction in the delay slot is executed. An FP condition code is set by the FP compare instruction, C.cond.fmt.

Restrictions:

Processor operation is **UNPREDICTABLE** if a branch, jump, ERET, DERET, or WAIT instruction is placed in the delay slot of a branch or jump.

Operation:

This operation specification is for the general Branch On Condition operation with the *tf* (true/false) and *nd* (nullify delay slot) fields as variables. The individual instructions BC1F, BC1FL, BC1T, and BC1TL have specific values for *tf* and *nd*.

```
I: condition ← FPConditionCode(cc) = 0
    target_offset ← (offset<sub>15</sub>)<sup>GPRLEN-(16+2)</sup> || offset || 0<sup>2</sup>
I+1: if condition then
    PC ← PC + target_offset
    endif
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Unimplemented Operation

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is \pm 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range

Historical Information:

The MIPS I architecture defines a single floating point condition code, implemented as the coprocessor 1 condition signal (*Cp1Cond*) and the *C* bit in the FP *Control/Status* register. MIPS I, II, and III architectures must have the *CC* field set to 0, which is implied by the first format in the "Format" section.

The MIPS IV and MIPS32 architectures add seven more *Condition Code* bits to the original condition code 0. FP compare and conditional branch instructions specify the *Condition Code* bit to set or test. Both assembler formats are valid for MIPS IV and MIPS32.

In the MIPS I, II, and III architectures there must be at least one instruction between the compare instruction that sets

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

the condition code and the branch instruction that tests it. Hardware does not detect a violation of this restriction.

| 31 | 26 | 25 21 | 20 1 | 8 17 | 16 | 15 | 0 |
|----|----------------|----------------------------|--------|---------|---------|--------|------------------|

    PC ← PC + target_offset
    else
        NullifyCurrentInstruction()
    endif
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Unimplemented Operation

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is \pm 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

Software is strongly encouraged to avoid the use of the Branch Likely instructions, as they will be removed from a future revision of the MIPS Architecture.

Some implementations always predict the branch will be taken, so there is a significant penalty if the branch is not taken. Software should only use this instruction when there is a very high probability (98% or more) that the branch will be taken. If the branch is not likely to be taken or if the probability of a taken branch is unknown, software is

encouraged to use the BC1F instruction instead.

Historical Information:

The MIPS I architecture defines a single floating point condition code, implemented as the coprocessor 1 condition signal (*Cp1Cond*) and the *C* bit in the FP *Control/Status* register. MIPS I, II, and III architectures must have the *CC* field set to 0, which is implied by the first format in the "Format" section.

The MIPS IV and MIPS32 architectures add seven more *Condition Code* bits to the original condition code 0. FP compare and conditional branch instructions specify the *Condition Code* bit to set or test. Both assembler formats are valid for MIPS IV and MIPS32.

In the MIPS II and III architectures, there must be at least one instruction between the compare instruction that sets a condition code and the branch instruction that tests it. Hardware does not detect a violation of this restriction.

Operation:

This operation specification is for the general Branch On Condition operation with the *tf* (true/false) and *nd* (nullify delay slot) fields as variables. The individual instructions BC2F, BC2FL, BC2T, and BC2TL have specific values for *tf* and *nd*.

```
I: condition ← COP2Condition(cc) = 0
    target_offset ← (offset<sub>15</sub>)<sup>GPRLEN-(16+2)</sup> || offset || 0<sup>2</sup>
I+1: if condition then
    PC ← PC + target_offset
    else
        NullifyCurrentInstruction()
    endif
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is \pm 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

Software is strongly encouraged to avoid the use of the Branch Likely instructions, as they will be removed from a future revision of the MIPS Architecture.

Some implementations always predict the branch will be taken, so there is a significant penalty if the branch is not taken. Software should only use this instruction when there is a very high probability (98% or more) that the branch will be taken. If the branch is not likely to be taken or if the probability of a taken branch is unknown, software is encouraged to use the BC2F instruction instead.

| | 6 | 5 | 3 | 1 | 1 | 16 | | |
| | | offset (cc = cc, offset | 0 implie | d) | | | MIPS32 MIPS32 | |

Purpose: Branch on COP2 True

To test a COP2 condition code and do a PC-relative conditional branch

Description: if COP2Condition(cc) = 1 then branch

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself) in the branch delay slot to form a PC-relative effective target address. If the COP2 condition specified by *cc* is true (1), the program branches to the effective target address after the instruction in the delay slot is executed.

Restrictions:

Processor operation is **UNPREDICTABLE** if a branch, jump, ERET, DERET, or WAIT instruction is placed in the delay slot of a branch or jump.

Operation:

This operation specification is for the general Branch On Condition operation with the *tf* (true/false) and *nd* (nullify delay slot) fields as variables. The individual instructions BC2F, BC2FL, BC2T, and BC2TL have specific values for *tf* and *nd*.

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is \pm 128 KBytes. Use jump and link (JAL) or jump and link register (JALR) instructions for procedure calls to addresses outside this range.

Software is strongly encouraged to avoid the use of the Branch Likely instructions, as they will be removed from a future revision of the MIPS Architecture.

Some implementations always predict the branch will be taken, so there is a significant penalty if the branch is not taken. Software should only use this instruction when there is a very high probability (98% or more) that the branch will be taken. If the branch is not likely to be taken or if the probability of a taken branch is unknown, software is encouraged to use the BLTZAL instruction instead.

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

Historical Information:

In the MIPS I architecture, this instruction signaled a Reserved Instruction Exception.

| 31 | 26 | 25 21 | 20 16 | 15 0 |
|----|------------------|-------|----------------|--------|
| | REGIMM 000001 | rs | BLTZL 00010 | offset |
| | 6 | 5 | 5 | 16 |

Format: BLTZL rs, offset

Purpose: Branch on Less Than Zero Likely

To test a GPR then do a PC-relative conditional branch; execute the delay slot only if the branch is taken.

Description: if GPR[rs] < 0 then branch_likely

An 18-bit signed offset (the 16-bit *offset* field shifted left 2 bits) is added to the address of the instruction following the branch (not the branch itself), in the branch delay slot, to form a PC-relative effective target address.

If the contents of GPR *rs* are less than zero (sign bit is 1), branch to the effective target address after the instruction in the delay slot is executed. If the branch is not taken, the instruction in the delay slot is not executed.

Restrictions:

Processor operation is **UNPREDICTABLE** if a branch, jump, ERET, DERET, or WAIT instruction is placed in the delay slot of a branch or jump.

Operation:

```
I: target_offset ← sign_extend(offset || 0<sup>2</sup>)
    condition ← GPR[rs] < 0<sup>GPRLEN</sup>
I+1: if condition then
    PC ← PC + target_offset
    else
        NullifyCurrentInstruction()
endif
```

Exceptions:

None

Programming Notes:

With the 18-bit signed instruction offset, the conditional branch range is \pm 128 KBytes. Use jump (J) or jump register (JR) instructions to branch to addresses outside this range.

Software is strongly encouraged to avoid the use of the Branch Likely instructions, as they will be removed from a future revision of the MIPS Architecture.

Some implementations always predict the branch will be taken, so there is a significant penalty if the branch is not taken. Software should only use this instruction when there is a very high probability (98% or more) that the branch will be taken. If the branch is not likely to be taken or if the probability of a taken branch is unknown, software is encouraged to use the BLTZ instruction instead.

To compare FP values and record the Boolean result in a condition code

Description: FPUConditionCode(cc) \leftarrow FPR[fs] compare_cond FPR[ft]

The value in FPR *fs* is compared to the value in FPR *ft*; the values are in format *fmt*. The comparison is exact and neither overflows nor underflows.

If the comparison specified by $cond_{2..1}$ is true for the operand values, the result is true; otherwise, the result is false. If no exception is taken, the result is written into condition code *CC*; true is 1 and false is 0.

c.cond.PS compares the upper and lower halves of FPR *fs* and FPR *ft* independently and writes the results into condition codes CC +1 and CC respectively. The CC number must be even. If the number is not even the operation of the instruction is **UNPREDICTABLE**.

If one of the values is an SNaN, or $cond_3$ is set and at least one of the values is a QNaN, an Invalid Operation condition is raised and the Invalid Operation flag is set in the *FCSR*. If the Invalid Operation *Enable* bit is set in the *FCSR*, no result is written and an Invalid Operation exception is taken immediately. Otherwise, the Boolean result is written into condition code *CC*.

There are four mutually exclusive ordering relations for comparing floating point values; one relation is always true and the others are false. The familiar relations are *greater than*, *less than*, and *equal*. In addition, the IEEE floating point standard defines the relation *unordered*, which is true when at least one operand value is NaN; NaN compares unordered with everything, including itself. Comparisons ignore the sign of zero, so +0 equals -0.

The comparison condition is a logical predicate, or equation, of the ordering relations such as *less than or equal*, *equal*, *not less than*, or *unordered or equal*. Compare distinguishes among the 16 comparison predicates. The Boolean result of the instruction is obtained by substituting the Boolean value of each ordering relation for the two FP values in the equation. If the *equal* relation is true, for example, then all four example predicates above yield a true result. If the *unordered* relation is true then only the final predicate, *unordered or equal*, yields a true result.

Logical negation of a compare result allows eight distinct comparisons to test for the 16 predicates as shown in Table 3.25. Each mnemonic tests for both a predicate and its logical negation. For each mnemonic, *compare* tests the truth of the first predicate. When the first predicate is true, the result is true as shown in the "If Predicate Is True" column, and the second predicate must be false, and vice versa. (Note that the False predicate is never true and False/True do not follow the normal pattern.)

The truth of the second predicate is the logical negation of the instruction result. After a compare instruction, test for the truth of the first predicate can be made with the Branch on FP True (BC1T) instruction and the truth of the second can be made with Branch on FP False (BC1F).

Table 3.26 shows another set of eight compare operations, distinguished by a $cond_3$ value of 1 and testing the same 16 conditions. For these additional comparisons, if at least one of the operands is a NaN, including Quiet NaN, then an Invalid Operation condition is raised. If the Invalid Operation condition is enabled in the *FCSR*, an Invalid Operation

Table 3.26 FPU Comparisons With Special Operand Exceptions for QNaNs

Restrictions:

The fields *fs* and *ft* must specify FPRs valid for operands of type *fmt*; if they are not valid, the result is **UNPREDICT-ABLE**.

The operands must be values in format *fmt*; if they are not, the result is **UNPREDICTABLE** and the value of the operand FPRs becomes **UNPREDICTABLE**.

The result of C.cond.PS is **UNPREDICTABLE** if the processor is executing in 16 FP registers mode, or if the condition code number is odd.

Operation:

```
if SNaN(ValueFPR(fs, fmt)) or SNaN(ValueFPR(ft, fmt)) or
      QNaN(ValueFPR(fs, fmt)) or QNaN(ValueFPR(ft, fmt)) then
      less ← false
      equal ← false
      unordered ← true
      if (SNaN(ValueFPR(fs, fmt)) or SNaN(ValueFPR(ft, fmt))) or
      (cond<sub>3</sub> and (QNaN(ValueFPR(fs, fmt)) or QNaN(ValueFPR(ft, fmt)))) then
        SignalException(InvalidOperation)
      endif
else
      less ← ValueFPR(fs, fmt) <<sub>fmt</sub> ValueFPR(ft, fmt)
      equal ← ValueFPR(fs, fmt) =<sub>fmt</sub> ValueFPR(ft, fmt)
      unordered ← false
endif
```

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

For c.cond.PS, the pseudo code above is repeated for both halves of the operand registers, treating each half as an independent single-precision values. Exceptions on the two halves are logically ORed and reported together. The results of the lower half comparison are written to condition code CC; the results of the upper half comparison are written to condition code CC; the results of the upper half comparison are written to condition code CC.

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Unimplemented Operation, Invalid Operation

Programming Notes:

FP computational instructions, including compare, that receive an operand value of Signaling NaN raise the Invalid Operation condition. Comparisons that raise the Invalid Operation condition for Quiet NaNs in addition to SNaNs permit a simpler programming model if NaNs are errors. Using these compares, programs do not need explicit code to check for QNaNs causing the *unordered* relation. Instead, they take an exception and allow the exception handling system to deal with the error when it occurs. For example, consider a comparison in which we want to know if two numbers are equal, but for which *unordered* would be an error.

```
# comparisons using explicit tests for QNaN
   c.eq.d $f2,$f4 # check for equal
   nop
              # it is equal
   bclt L2
   c.un.d $f2,$f4 # it is not equal,
  # but might be unordered
bc1t ERROR # unordered goes off to an error handler
# not-equal-case code here
  . . .
# equal-case code here
L2:
# comparison using comparisons that signal QNaN
   c.seq.d $f2,$f4 # check for equal
   nop
            # it is equal
   bc1t
        L2
   nop
# it is not unordered here
   . . .
# not-equal-case code here
   . . .
# equal-case code here
```

| 31 | 26 25 | 21 20 | 16 15 | 0 |
|-----------------|---------------|---------|--------|--------|
| CACHE 101111 | base | op | offset | |
| 6 | 5 | 5 | 16 | |
| Format: CAC | CHE op, offse | t(base) | | MIPS32 |

Purpose: Perform Cache Operation

To perform the cache operation specified by op.

Description:

The 16-bit offset is sign-extended and added to the contents of the base register to form an effective address. The effective address is used in one of the following ways based on the operation to be performed and the type of cache as described in the following table.

| Operation Requires an | Type of Cache | Usage of Effective Address |
|--------------------------|------------------|---|
| Address | Virtual | The effective address is used to address the cache. An address translation may or may not be performed on the effective address (with the possibility that a TLB Refill or TLB Invalid exception might occur) |
| Address | Physical | The effective address is translated by the MMU to a physical address. The physical address is then used to address the cache |
| Index | N/A | The effective address is translated by the MMU to a physical address. It is imple- mentation dependent whether the effective address or the translated physical address is used to index the cache. As such, a kseg0 address should always be used for cache operations that require an index. See the Programming Notes sec- tion below. |
| | | Assuming that the total cache size in bytes is CS, the associativity is A, and the number of bytes per tag is BPT, the following calculations give the fields of the address which specify the way and the index: |
| | | OffsetBit ← Log2(BPT) IndexBit ← Log2(CS / A) WayBit ← IndexBit + Ceiling(Log2(A)) Way ← Addr _{WayBit-1IndexBit} Index ← Addr _{IndexBit-1OffsetBit} For a direct-mapped cache, the Way calculation is ignored and the Index value fully specifies the cache tag. This is shown symbolically in the figure below. |
| | | rany specifies are cache ag. This is shown symbolicany in the lighte below. |

Table 3.27 Usage of Effective Address

Figure 3.2 Usage of Address Fields to Select Index and Way

A TLB Refill and TLB Invalid (both with cause code equal TLBL) exception can occur on any operation. For index operations (where the address is used to index the cache but need not match the cache tag) software should use unmapped addresses to avoid TLB exceptions. This instruction never causes TLB Modified exceptions nor TLB Refill exceptions with a cause code of TLBS.

The effective address may be an arbitrarily-aligned by address. The CACHE instruction never causes an Address Error Exception due to an non-aligned address.

A Cache Error exception may occur as a by-product of some operations performed by this instruction. For example, if a Writeback operation detects a cache or bus error during the processing of the operation, that error is reported via a Cache Error exception. Similarly, a Bus Error Exception may occur if a bus operation invoked by this instruction is terminated in an error. However, cache error exceptions must not be triggered by an Index Load Tag or Index Store tag operation, as these operations are used for initialization and diagnostic purposes.

An Address Error Exception (with cause code equal AdEL) may occur if the effective address references a portion of the kernel address space which would normally result in such an exception. It is implementation dependent whether such an exception does occur.

It is implementation dependent whether a data watch is triggered by a cache instruction whose address matches the Watch register address match conditions.

The CACHE instruction and the memory transactions which are sourced by the CACHE instruction, such as cache refill or cache writeback, obey the ordering and completion rules of the SYNC instruction.

Bits [17:16] of the instruction specify the cache on which to perform the operation, as follows:

| Code | Name | Cache |
|------|------|---------------------------------|
| 0b00 | Ι | Primary Instruction |
| 0b01 | D | Primary Data or Unified Primary |
| 0b10 | Т | Tertiary |
| 0b11 | S | Secondary |

Table 3.28 Encoding of Bits[17:16] of CACHE Instruction

Bits [20:18] of the instruction specify the operation to perform. To provide software with a consistent base of cache operations, certain encodings must be supported on all processors. The remaining encodings are recommended

For implementations which implement multiple level of caches and where the hardware maintains the smaller cache as a proper subset of a larger cache (every address which is resident in the smaller cache is also resident in the larger cache; also known as the inclusion property), it is recommended that the CACHE instructions which operate on the larger, outer-level cache; should first operate on the smaller, inner-level cache. For example, a Hit_Writeback _Invalidate operation targeting the Secondary cache, should first operate on the primary data cache first. If the CACHE instruction implementation does not follow this policy then any software which flushes the caches must mimic this behavior. That is, the software sequences must first operate on the inner cache then operate on the outer cache. The software must place a SYNC instruction after the CACHE instruction whenever there are possible writebacks from the inner cache to ensure that the writeback data is resident in the outer cache before operating on the outer cache. If neither the CACHE instruction implementation nor the software cache flush sequence follow this policy, then the inclusion property of the caches can be broken, which might be a condition that the cache management hardware can not properly deal with.

For implementations which implement multiple level of caches without the inclusion property, the use of a SYNC instruction after the CACHE instruction is still needed whenever writeback data has to be resident in the next level of memory hierarchy.

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

For multiprocessor implementations that maintain coherent caches, some of the Hit type of CACHE instruction operations may optionally affect all coherent caches within the implementation. If the effective address uses a coherent Cache Coherency Attribute (CCA), then the operation is *globalized*, meaning it is broadcast to all of the coherent caches within the system. If the effective address does not use one of the coherent CCAs, there is no broadcast of the operation. If multiple levels of caches are to be affected by one CACHE instruction, all of the affected cache levels must be processed in the same manner - either all affected cache levels use the globalized behavior or all affected cache levels use the non-globalized behavior.

Table 3.29 Encoding of Bits [20:18] of the CACHE Instruction

| Code | Caches | Name | Effective Address Operand Type | Operation | Compliance Implemented |
|-------|--------|---|---|--|---|
| 0Ь000 | Ι | Index Invalidate | Index | Set the state of the cache block at the specified index to invalid. This required encoding may be used by soft- ware to invalidate the entire instruction cache by stepping through all valid indices. | Required |
| | D | Index Writeback Invalidate / Index Invalidate | Index | For a write-back cache: If the state of the cache block at the specified index is valid and dirty, write the block back to the memory address specified by the cache tag. After that | Required |
| | S, T | Index Writeback Invalidate / Index Invalidate | Index | operation is completed, set the state of the cache block to invalid. If the block is valid but not dirty, set the state of the block to invalid. For a write-through cache: Set the state of the cache block at the specified index to invalid. This required encoding may be used by software to invalidate the entire data cache by stepping through all valid indices. Note that Index Store Tag should be used to initialize the cache at power up. | Required if S, T cache is imple- mented |
| 06001 | All | Index Load Tag | Index | Read the tag for the cache block at the speci- fied index into the <i>TagLo</i> and <i>TagHi</i> Copro- cessor 0 registers. If the <i>DataLo</i> and <i>DataHi</i> registers are implemented, also read the data corresponding to the byte index into the <i>DataLo</i> and <i>DataHi</i> registers. This operation must not cause a Cache Error Exception. The granularity and alignment of the data read into the <i>DataLo</i> and <i>DataHi</i> registers is implementation-dependent, but is typically the result of an aligned access to the cache, ignor- ing the appropriate low-order bits of the byte index. | Recommended |

Table 3.29 Encoding of Bits [20:18] of the CACHE Instruction (Continued)

| Code | Caches | Name | Effective Address Operand Type | Operation | Compliance Implemented |
|-------|--------|---|---|--|---|
| 0Ь010 | All | Index Store Tag | Index | Write the tag for the cache block at the speci- fied index from the <i>TagLo</i> and <i>TagHi</i> Copro- cessor 0 registers. This operation must not cause a Cache Error Exception. This required encoding may be used by soft- ware to initialize the entire instruction or data caches by stepping through all valid indices. Doing so requires that the <i>TagLo</i> and <i>TagHi</i> registers associated with the cache be initial- ized first. | Required |
| 0b011 | All | Implementation Dependent | Unspecified | Available for implementation-dependent oper- ation. | Optional |
| 0b100 | I, D | Hit Invalidate | Address | If the cache block contains the specified address, set the state of the cache block to invalid. This required encoding may be used by soft- ware to invalidate a range of addresses from the instruction cache by stepping through the | Required (Instruc- tion Cache Encod- ing Only), Recommended oth- erwise |
| | S, T | Hit Invalidate | Address | address range by the line size of the cache. In multiprocessor implementations with coher- ent caches, the operation may optionally be broadcast to all coherent caches within the sys- tem. | Optional, if Hit_Invalidate_D is implemented, the S and T variants are recommended. |
| 0b101 | I | Fill | Address | Fill the cache from the specified address. | Recommended |
| | D | Hit Writeback Invalidate / Hit Invalidate | Address | For a write-back cache: If the cache block con- tains the specified address and it is valid and dirty, write the contents back to memory. After that operation is completed, set the state of the | Required |
| | S, T | Hit Writeback Invalidate / Hit Invalidate | Address | cache block to invalid. If the block is valid but not dirty, set the state of the block to invalid. For a write-through cache: If the cache block contains the specified address, set the state of the cache block to invalid. This required encoding may be used by soft- ware to invalidate a range of addresses from the data cache by stepping through the address range by the line size of the cache. In multiprocessor implementations with coher- ent caches, the operation may optionally be broadcast to all coherent caches within the sys- tem. | Required if S, T cache is imple- mented |

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

Table 3.29 Encoding of Bits [20:18] of the CACHE Instruction (Continued)

| Code | Caches | Name | Effective Address Operand Type | Operation | Compliance Implemented |
|-------|--------|----------------|---|---|--|
| 0b110 | D | Hit Writeback | Address | If the cache block contains the specified address and it is valid and dirty, write the con- | Recommended |
| | S, T | Hit Writeback | Address | tents back to memory. After the operation is completed, leave the state of the line valid, but clear the dirty state. For a write-through cache, this operation may be treated as a nop. In multiprocessor implementations with coherent caches, the operation may optionally be broadcast to all coherent caches within the system. | Optional, if Hit_Writeback_D is implemented, the S and T variants are recommended. |
| Ob111 | I, D | Fetch and Lock | Address | If the cache does not contain the specified address, fill it from memory, performing a writeback if required, and set the state to valid and locked. If the cache already contains the specified address, set the state to locked. In set-associative or fully-associative caches, the way selected on a fill from memory is imple- mentation dependent. The lock state may be cleared by executing an Index Invalidate, Index Writeback Invalidate, Hit Invalidate, or Hit Writeback Invalidate operation to the locked line, or via an Index Store Tag operation to the line that clears the lock bit. Note that clearing the lock state via Index Store Tag is dependent on the imple- mentation-dependent cache tag and cache line organization, and that Index and Index Write- back Invalidate operations are dependent on cache line organization. Only Hit and Hit Writeback Invalidate operations are generally portable across implementations. It is implementation dependent whether a locked line is displaced as the result of an external invalidate or intervention that hits on the locked line. Software must not depend on the locked line remaining in the cache if an external invalidate or intervention would invalidate the line if it were not locked. It is implementation dependent whether a Fetch and Lock operation affects more than one line. For example, more than one line around the referenced address may be fetched and locked. It is recommended that only the single line containing the referenced address be affected. | Recommended |

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

Restrictions:

The operation of this instruction is **UNDEFINED** for any operation/cache combination that is not implemented.

The operation of this instruction is **UNDEFINED** if the operation requires an address, and that address is uncacheable.

The operation of the instruction is **UNPREDICTABLE** if the cache line that contains the CACHE instruction is the target of an invalidate or a writeback invalidate.

If this instruction is used to lock all ways of a cache at a specific cache index, the behavior of that cache to subsequent cache misses to that cache index is **UNDEFINED**.

If access to Coprocessor 0 is not enabled, a Coprocessor Unusable Exception is signaled.

Any use of this instruction that can cause cacheline writebacks should be followed by a subsequent SYNC instruction to avoid hazards where the writeback data is not yet visible at the next level of the memory hierarchy.

Operation:

```
vAddr ← GPR[base] + sign_extend(offset)
(pAddr, uncached) ← AddressTranslation(vAddr, DataReadReference)
CacheOp(op, vAddr, pAddr)
```

Exceptions:

TLB Refill Exception.

TLB Invalid Exception

Coprocessor Unusable Exception

Address Error Exception

Cache Error Exception

Bus Error Exception

Programming Notes:

For cache operations that require an index, it is implementation dependent whether the effective address or the translated physical address is used as the cache index. Therefore, the index value should always be converted to a kseg0 address by ORing the index with 0x80000000 before being used by the cache instruction. For example, the following code sequence performs a data cache Index Store Tag operation using the index passed in GPR a0:

| li | al, 0x80000000 | /* Base of kseg0 segment */ |
|-------|---------------------|---|
| or | a0, a0, a1 | /* Convert index to kseg0 address */ |
| cache | DCIndexStTag, 0(a1) | /* Perform the index store tag operation */ |

| 31 | 26 | 25 | 21 | 20 16 | 15 11 | 10 6 | 5 0 |
|--------------|-------|------------------|----|------------|--------------------|--------------|--------------------------|
| COP 01000 | | fmt | | 0 00000 | fs | fd | CEIL.L 001010 |
| 6 | | 5 | | 5 | 5 | 5 | 6 |
| Format: | CEIL. | L.fmt L.S fd, | fs | MIPS64, MI | PS32 Release 2CEII | L.L.D fd, fs | MIPS64, MIPS32 Release 2 |

Purpose: Fixed Point Ceiling Convert to Long Fixed Point

To convert an FP value to 64-bit fixed point, rounding up

Description: FPR[fd] ← convert_and_round(FPR[fs])

The value in FPR *fs*, in format *fmt*, is converted to a value in 64-bit long fixed point format and rounding toward $+\infty$ (rounding mode 2). The result is placed in FPR *fd*.

When the source value is Infinity, NaN, or rounds to an integer outside the range -2^{63} to 2^{63} -1, the result cannot be represented correctly, an IEEE Invalid Operation condition exists, and the Invalid Operation flag is set in the *FCSR*. If the Invalid Operation *Enable* bit is set in the *FCSR*, no result is written to *fd* and an Invalid Operation exception is taken immediately. Otherwise, the default result, 2^{63} -1, is written to *fd*.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs; *fs* for type *fmt* and *fd* for long fixed point; if they are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fint*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of this instruction is **UNPREDICTABLE** if the processor is executing in 16 FP registers mode.

Operation:

```
StoreFPR(fd, L, ConvertFmt(ValueFPR(fs, fmt), fmt, L))
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Invalid Operation, Unimplemented Operation, Inexact, Overflow

| 31 | 26 | 25 | | 21 | 20 | 16 | 15 | 11 | 10 | 6 | 5 | 0 |

| | | | | | | | | | | | | |

Purpose: Floating Point Ceiling Convert to Word Fixed Point

To convert an FP value to 32-bit fixed point, rounding up

Description: FPR[fd] \leftarrow convert_and_round(FPR[fs])

The value in FPR *fs*, in format *fmt*, is converted to a value in 32-bit word fixed point format and rounding toward $+\infty$ (rounding mode 2). The result is placed in FPR *fd*.

When the source value is Infinity, NaN, or rounds to an integer outside the range -2^{31} to 2^{31} -1, the result cannot be represented correctly, an IEEE Invalid Operation condition exists, and the Invalid Operation flag is set in the *FCSR*. If the Invalid Operation *Enable* bit is set in the *FCSR*, no result is written to *fd* and an Invalid Operation exception is taken immediately. Otherwise, the default result, 2^{31} -1, is written to *fd*.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs; *fs* for type *fmt* and *fd* for word fixed point; if they are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fint*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

Operation:

```
StoreFPR(fd, W, ConvertFmt(ValueFPR(fs, fmt), fmt, W))
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Invalid Operation, Unimplemented Operation, Inexact, Overflow

| 6 | 5 | | 5 | 5 | 11 |

Format: CFC1 rt, fs

Purpose: Move Control Word From Floating Point

To copy a word from an FPU control register to a GPR

Description: GPR[rt] ← FP_Control[fs]

Copy the 32-bit word from FP (coprocessor 1) control register fs into GPR rt.

Restrictions:

There are a few control registers defined for the floating point unit. The result is **UNPREDICTABLE** if *fs* specifies a register that does not exist.

Operation:

```
if fs = 0 then

temp \leftarrow FIR

elseif fs = 25 then

temp \leftarrow 0^{24} \mid \mid \text{FCSR}_{31..25} \mid \mid \text{FCSR}_{23}

elseif fs = 26 then

temp \leftarrow 0^{14} \mid \mid \text{FCSR}_{17..12} \mid \mid 0^5 \mid \mid \text{FCSR}_{6..2} \mid \mid 0^2

elseif fs = 28 then

temp \leftarrow 0^{20} \mid \mid \text{FCSR}_{11.7} \mid \mid 0^4 \mid \mid \text{FCSR}_{24} \mid \mid \text{FCSR}_{1..0}

elseif fs = 31 then

temp \leftarrow \text{FCSR}

else

temp \leftarrow \text{UNPREDICTABLE}

endif

GPR[rt] \leftarrow temp
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Historical Information:

For the MIPS I, II and III architectures, the contents of GPR *rt* are **UNPREDICTABLE** for the instruction immediately following CFC1.

MIPS V and MIPS32 introduced the three control registers that access portions of FCSR. These registers were not available in MIPS I, II, III, or IV.

| : | 31 | 26 | 25 | 21 | 20 16 | 15 11 10 0 | |

| | Format: CF | C2 : | rt, Impl | | | MIP | PS32 |

The syntax shown above is an example using CFC1 as a model. The specific syntax is implementation dependent.

Purpose: Move Control Word From Coprocessor 2

To copy a word from a Coprocessor 2 control register to a GPR

Description: GPR[rt] ← CP2CCR[Impl]

Copy the 32-bit word from the Coprocessor 2 control register denoted by the *Impl* field. The interpretation of the *Impl* field is left entirely to the Coprocessor 2 implementation and is not specified by the architecture.

Restrictions:

The result is UNPREDICTABLE if *Impl* specifies a register that does not exist.

Operation:

 $\begin{array}{l} \texttt{temp} \leftarrow \texttt{CP2CCR[Impl]} \\ \texttt{GPR[rt]} \leftarrow \texttt{temp} \end{array}$

Exceptions:

Coprocessor Unusable, Reserved Instruction

| Format: CLO rd, rs MI | | | | | | | | | | MIPS32 |

Purpose: Count Leading Ones in Word

To count the number of leading ones in a word

Description: GPR[rd] ← count_leading_ones GPR[rs]

Bits 31..0 of GPR *rs* are scanned from most significant to least significant bit. The number of leading ones is counted and the result is written to GPR *rd*. If all of bits **31..0** were set in GPR *rs*, the result written to GPR *rd* is 32.

Restrictions:

To be compliant with the MIPS32 and MIPS64 Architecture, software must place the same GPR number in both the *rt* and *rd* fields of the instruction. The operation of the instruction is **UNPREDICTABLE** if the *rt* and *rd* fields of the instruction contain different values.

Operation:

```
temp \leftarrow 32
for i in 31 .. 0
if GPR[rs]<sub>i</sub> = 0 then
temp \leftarrow 31 - i
break
endif
endfor
GPR[rd] \leftarrow temp

| 6 | | 5 | | 5 | 5 | | 11 |

Format: CTC1 rt, fs

Purpose: Move Control Word to Floating Point

To copy a word from a GPR to an FPU control register

Description: FP_Control[fs] ← GPR[rt]

Copy the low word from GPR rt into the FP (coprocessor 1) control register indicated by fs.

Writing to the floating point *Control/Status* register, the *FCSR*, causes the appropriate exception if any *Cause* bit and its corresponding *Enable* bit are both set. The register is written before the exception occurs. Writing to *FEXR* to set a cause bit whose enable bit is already set, or writing to *FENR* to set an enable bit whose cause bit is already set causes the appropriate exception. The register is written before the exception occurs and the *EPC* register contains the address of the CTC1 instruction.

Restrictions:

There are a few control registers defined for the floating point unit. The result is **UNPREDICTABLE** if *fs* specifies a register that does not exist.

Operation:

```
\texttt{temp} \leftarrow \texttt{GPR[rt]}_{31..0}

Purpose: Floating Point Convert to Double Floating Point

To convert an FP or fixed point value to double FP

Description: FPR[fd] ← convert_and_round(FPR[fs])

The value in FPR *fs*, in format *fmt*, is converted to a value in double floating point format and rounded according to the current rounding mode in *FCSR*. The result is placed in FPR *fd*. If *fmt* is S or W, then the operation is always exact.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs—*fs* for type *fmt* and *fd* for double floating point—if they are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

For CVT.D.L, the result of this instruction is **UNPREDICTABLE** if the processor is executing in 16 FP registers mode.

Operation:

StoreFPR (fd, D, ConvertFmt(ValueFPR(fs, fmt), fmt, D))

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Invalid Operation, Unimplemented Operation, Inexact

Purpose: Floating Point Convert to Long Fixed Point

To convert an FP value to a 64-bit fixed point

Description: FPR[fd] ← convert_and_round(FPR[fs])

Convert the value in format *fmt* in FPR *fs* to long fixed point format and round according to the current rounding mode in *FCSR*. The result is placed in FPR *fd*.

When the source value is Infinity, NaN, or rounds to an integer outside the range -2^{63} to 2^{63} -1, the result cannot be represented correctly, an IEEE Invalid Operation condition exists, and the Invalid Operation flag is set in the *FCSR*. If the Invalid Operation *Enable* bit is set in the *FCSR*, no result is written to *fd* and an Invalid Operation exception is taken immediately. Otherwise, the default result, 2^{63} -1, is written to *fd*.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs—*fs* for type *fmt* and *fd* for long fixed point—if they are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of this instruction is **UNPREDICTABLE** if the processor is executing in 16 FP registers mode.

Operation:

StoreFPR (fd, L, ConvertFmt(ValueFPR(fs, fmt), fmt, L))

Exceptions:

Coprocessor Unusable, Reserved Instruction

| 6 | | 5 | | 5 | | | 5 | | 5 | | | 6 | |

Format: CVT.PS.S fd, fs, ft

Purpose: Floating Point Convert Pair to Paired Single

To convert two FP values to a paired single value

Description: FPR[fd] ← FPR[fs]_{31..0} || FPR[ft]_{31..0}

The single-precision values in FPR *fs* and *ft* are written into FPR *fd* as a paired-single value. The value in FPR *fs* is written into the upper half, and the value in FPR *ft* is written into the lower half.

CVT.PS.S is similar to PLL.PS, except that it expects operands of format S instead of PS.

The move is non-arithmetic; it causes no IEEE 754 exceptions.

Restrictions:

The fields *fs* and *ft* must specify FPRs valid for operands of type *S*; if they are not valid, the result is **UNPREDICT-ABLE**.

The operand must be a value in format *S*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of this instruction is UNPREDICTABLE if the processor is executing in 16 FP registers mode.

Operation:

StoreFPR(fd, S, ValueFPR(fs,S) || ValueFPR(ft,S))

Exceptions:

Format: CVT.S.PU fd, fs

Purpose: Floating Point Convert Pair Upper to Single Floating Point

To convert one half of a paired single FP value to single FP

Description: $FPR[fd] \leftarrow FPR[fs]_{63..32}$

The upper paired single value in FPR *fs*, in format *PS*, is converted to a value in single floating point format. The result is placed in FPR *fd*. This instruction can be used to isolate the upper half of a paired single value.

The operation is non-arithmetic; it causes no IEEE 754 exceptions.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs—*fs* for type *PS* and *fd* for single floating point. If they are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *PS*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of CVT.S.PU is UNPREDICTABLE if the processor is executing in 16 FP registers mode.

Operation:

StoreFPR (fd, S, ConvertFmt(ValueFPR(fs, PS), PU, S))

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

MIPS64, MIPS32 Release 2

| 1 | 26 | 25 | 21 | 20 | 16 | 15 11 | 10 6 | 5 | 0 |

| Format: CVT.W.fmt CVT.W.S fd, fs CVT.W.D fd, fs | | | | | | | | | MIPS32 MIPS32 |

Purpose: Floating Point Convert to Word Fixed Point

To convert an FP value to 32-bit fixed point

Description: FPR[fd] ← convert_and_round(FPR[fs])

The value in FPR *fs*, in format *fmt*, is converted to a value in 32-bit word fixed point format and rounded according to the current rounding mode in *FCSR*. The result is placed in FPR *fd*.

When the source value is Infinity, NaN, or rounds to an integer outside the range -2^{31} to 2^{31} -1, the result cannot be represented correctly, an IEEE Invalid Operation condition exists, and the Invalid Operation flag is set in the *FCSR*. If the Invalid Operation *Enable* bit is set in the *FCSR*, no result is written to *fd* and an Invalid Operation exception is taken immediately. Otherwise, the default result, 2^{31} -1, is written to *fd*.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs—*fs* for type *fmt* and *fd* for word fixed point—if they are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fint*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

Operation:

```
StoreFPR(fd, W, ConvertFmt(ValueFPR(fs, fmt), fmt, W))
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Invalid Operation, Unimplemented Operation, Inexact, Overflow

EJTAG

| 31 | 26 25 | 24 6 | 5 (| 0 |
|-------------|--------|----------------------------|-------------|---|
| COP0 | CO | 0 | DERET | |
| 010000 6 | 1 1 | 000 0000 0000 0000 0000 19 | 011111 6 | |

Format: DERET

Purpose: Debug Exception Return

To Return from a debug exception.

Description:

DERET clears execution and instruction hazards, returns from Debug Mode and resumes non-debug execution at the instruction whose address is contained in the *DEPC* register. DERET does not execute the next instruction (i.e. it has no delay slot).

Restrictions:

A DERET placed between an LL and SC instruction does not cause the SC to fail.

If the *DEPC* register with the return address for the DERET was modified by an MTC0 or a DMTC0 instruction, a CP0 hazard exists that must be removed via software insertion of the appropriate number of SSNOP instructions (for implementations of Release 1 of the Architecture) or by an EHB, or other execution hazard clearing instruction (for implementations of Release 2 of the Architecture).

DERET implements a software barrier that resolves all execution and instruction hazards created by Coprocessor 0 state changes (for Release 2 implementations, refer to the SYNCI instruction for additional information on resolving instruction hazards created by writing the instruction stream). The effects of this barrier are seen starting with the instruction fetch and decode of the instruction at the PC to which the DERET returns.

This instruction is legal only if the processor is executing in Debug Mode. The operation of the processor is **UNDE-FINED** if a DERET is executed in the delay slot of a branch or jump instruction.

Operation:

```
\begin{split} & \text{Debug}_{\text{DM}} \leftarrow 0 \\ & \text{Debug}_{\text{IEXI}} \leftarrow 0 \\ & \text{if ISMIPS16Implemented()} \mid (\text{Config3}_{\text{ISA}} > 0) \text{ then} \\ & \text{PC} \leftarrow \text{DEPC}_{31..1} \mid \mid 0 \\ & \text{ISAMode} \leftarrow \text{DEPC}_{0} \\ & \text{else} \\ & \text{PC} \leftarrow \text{DEPC} \\ & \text{endif} \\ & \text{ClearHazards()} \end{split}
```

Exceptions:

Coprocessor Unusable Exception Reserved Instruction Exception

| 31 | | 26 | 25 | | 21 | 20 | 16 | 15 | | 11 | 10 | | 6 | 5 | 4 | 3 | 2 | 0 | |

| | 6 | | | 5 | | 5 | | | 5 | | | 5 | | 1 | 2 | | | 3 | |
| | Format: DI DI | rt | | | | | | | | | | | | | | | | 32 Rel 32 Rel | |

Purpose: Disable Interrupts

To return the previous value of the *Status* register and disable interrupts. If DI is specified without an argument, GPR r0 is implied, which discards the previous value of the Status register.

Description: GPR[rt] \leftarrow Status; Status_{IE} \leftarrow 0

The current value of the *Status* register is loaded into general register *rt*. The Interrupt Enable (IE) bit in the *Status* register is then cleared.

Restrictions:

If access to Coprocessor 0 is not enabled, a Coprocessor Unusable Exception is signaled.

In implementations prior to Release 2 of the architecture, this instruction resulted in a Reserved Instruction Exception.

Operation:

This operation specification is for the general interrupt enable/disable operation, with the *sc* field as a variable. The individual instructions DI and EI have a specific value for the *sc* field.

```
data \leftarrow Status
GPR[rt] \leftarrow data
Status<sub>IE</sub> \leftarrow 0
```

Exceptions:

Coprocessor Unusable Reserved Instruction (Release 1 implementations)

Programming Notes:

The effects of this instruction are identical to those accomplished by the sequence of reading *Status* into a GPR, clearing the IE bit, and writing the result back to *Status*. Unlike the multiple instruction sequence, however, the DI instruction can not be aborted in the middle by an interrupt or exception.

This instruction creates an execution hazard between the change to the Status register and the point where the change to the interrupt enable takes effect. This hazard is cleared by the EHB, JALR.HB, JR.HB, or ERET instructions. Software must not assume that a fixed latency will clear the execution hazard.

| | Format: DI | V r | s, rt | | | | | | | | MIPS32 |

Purpose: Divide Word

To divide a 32-bit signed integers

Description: (HI, LO) ← GPR[rs] / GPR[rt]

The 32-bit word value in GPR rs is divided by the 32-bit value in GPR rt, treating both operands as signed values. The 32-bit quotient is placed into special register LO and the 32-bit remainder isplaced into special register HI.

No arithmetic exception occurs under any circumstances.

Restrictions:

If the divisor in GPR rt is zero, the arithmetic result value is UNPREDICTABLE.

Operation:

```
\begin{array}{rcl} q & \leftarrow & \operatorname{GPR}[\operatorname{rs}]_{31..0} & \operatorname{div} & \operatorname{GPR}[\operatorname{rt}]_{31..0} \\ \operatorname{LO} & \leftarrow & q \\ r & \leftarrow & \operatorname{GPR}[\operatorname{rs}]_{31..0} & \operatorname{mod} & \operatorname{GPR}[\operatorname{rt}]_{31..0} \\ \operatorname{HI} & \leftarrow & r \end{array}
```

Exceptions:

None

Programming Notes:

No arithmetic exception occurs under any circumstances. If divide-by-zero or overflow conditions are detected and some action taken, then the divide instruction is typically followed by additional instructions to check for a zero divisor and/or for overflow. If the divide is asynchronous then the zero-divisor check can execute in parallel with the divide. The action taken on either divide-by-zero or overflow is either a convention within the program itself, or more typically within the system software; one possibility is to take a BREAK exception with a *code* field value to signal the problem to the system software.

As an example, the C programming language in a UNIX® environment expects division by zero to either terminate the program or execute a program-specified signal handler. C does not expect overflow to cause any exceptional condition. If the C compiler uses a divide instruction, it also emits code to test for a zero divisor and execute a BREAK instruction to inform the operating system if a zero is detected.

By default, most compilers for the MIPS architecture will emit additional instructions to check for the divide-by-zero and overflow cases when this instruction is used. In many compilers, the assembler mnemonic "DIV r0, rs, rt" can be used to prevent these additional test instructions to be emitted.

In some processors the integer divide operation may proceed asynchronously and allow other CPU instructions to execute before it is complete. An attempt to read LO or HI before the results are written interlocks until the results are ready. Asynchronous execution does not affect the program result, but offers an opportunity for performance improvement by scheduling the divide so that other instructions can execute in parallel.

Historical Perspective:

In MIPS 1 through MIPS III, if either of the two instructions preceding the divide is an MFHI or MFLO, the result of the MFHI or MFLO is **UNPREDICTABLE**. Reads of the *HI* or *LO* special register must be separated from subse-

| Format: | DIV.S | fd, f | Es, ft Es, ft | | | | | MIPS32 MIPS32 |

Purpose: Floating Point Divide

To divide FP values

Description: FPR[fd] ← FPR[fs] / FPR[ft]

The value in FPR *fs* is divided by the value in FPR *ft*. The result is calculated to infinite precision, rounded according to the current rounding mode in *FCSR*, and placed into FPR *fd*. The operands and result are values in format *fmt*.

Restrictions:

The fields *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *fmt*; if they are not valid, the result is **UNPRED**-ICABLE.

The operands must be values in format *fmt*; if they are not, the result is **UNPREDICTABLE** and the value of the operand FPRs becomes **UNPREDICTABLE**.

Operation:

StoreFPR (fd, fmt, ValueFPR(fs, fmt) / ValueFPR(ft, fmt))

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Format: DIVU rs, rt

Purpose: Divide Unsigned Word

To divide a 32-bit unsigned integers

Description: (HI, LO) ← GPR[rs] / GPR[rt]

The 32-bit word value in GPR rs is divided by the 32-bit value in GPR rt, treating both operands as unsigned values. The 32-bit quotient is placed into special register LO and the 32-bit remainder is placed into special register HI.

No arithmetic exception occurs under any circumstances.

Restrictions:

If the divisor in GPR *rt* is zero, the arithmetic result value is **UNPREDICTABLE**.

Operation:

```
q \leftarrow (0 \mid | GPR[rs]_{31..0}) \text{ div } (0 \mid | GPR[rt]_{31..0})
r \leftarrow (0 \mid | GPR[rs]_{31..0}) \mod (0 \mid | GPR[rt]_{31..0})
L0 \leftarrow sign_extend(q<sub>31..0</sub>)
\text{HI} \leftarrow \text{sign\_extend}(r_{31,..0})
```

Exceptions:

None

Programming Notes:

See "Programming Notes" for the DIV instruction.

Historical Perspective:

In MIPS 1 through MIPS III, if either of the two instructions preceding the divide is an MFHI or MFLO, the result of the MFHI or MFLO is UNPREDICTABLE. Reads of the HI or LO special register must be separated from subsequent instructions that write to them by two or more instructions. This restriction was removed in MIPS IV and MIPS32 and all subsequent levels of the architecture.

| 6 | | 5 | | 5 | 5 | | 5 | 6 | |

Format: EHB

MIPS32 Release 2

Purpose: Execution Hazard Barrier

To stop instruction execution until all execution hazards have been cleared.

Description:

EHB is the assembly idiom used to denote execution hazard barrier. The actual instruction is interpreted by the hardware as SLL r0, r0, 3.

This instruction alters the instruction issue behavior on a pipelined processor by stopping execution until all execution hazards have been cleared. Other than those that might be created as a consequence of setting $Status_{CU0}$, there are no execution hazards visible to an unprivileged program running in User Mode. All execution hazards created by previous instructions are cleared for instructions executed immediately following the EHB, even if the EHB is executed in the delay slot of a branch or jump. The EHB instruction does not clear instruction hazards—such hazards are cleared by the JALR.HB, JR.HB, and ERET instructions.

Restrictions:

None

Operation:

ClearExecutionHazards()

Exceptions:

None

Programming Notes:

In MIPS32 Release 2 implementations, this instruction resolves all execution hazards. On a superscalar processor, EHB alters the instruction issue behavior in a manner identical to SSNOP. For backward compatibility with Release 1 implementations, the last of a sequence of SSNOPs can be replaced by an EHB. In Release 1 implementations, the EHB will be treated as an SSNOP, thereby preserving the semantics of the sequence. In Release 2 implementations, replacing the final SSNOP with an EHB should have no performance effect because a properly sized sequence of SSNOPs will have already cleared the hazard. As EHB becomes the standard in MIPS implementations, the previous SSNOPs can be removed, leaving only the EHB.

| | Format: EI EI | rt | | | | | | | | | | | | | | 832 Rel 832 Rel | |

Purpose: Enable Interrupts

To return the previous value of the *Status* register and enable interrupts. If EI is specified without an argument, GPR r0 is implied, which discards the previous value of the Status register.

Description: GPR[rt] \leftarrow Status; Status_{IE} \leftarrow 1

The current value of the *Status* register is loaded into general register *rt*. The Interrupt Enable (IE) bit in the *Status* register is then set.

Restrictions:

If access to Coprocessor 0 is not enabled, a Coprocessor Unusable Exception is signaled.

In implementations prior to Release 2 of the architecture, this instruction resulted in a Reserved Instruction Exception.

Operation:

This operation specification is for the general interrupt enable/disable operation, with the *sc* field as a variable. The individual instructions DI and EI have a specific value for the *sc* field.

```
data \leftarrow Status
GPR[rt] \leftarrow data
Status<sub>IE</sub> \leftarrow 1
```

Exceptions:

Coprocessor Unusable Reserved Instruction (Release 1 implementations)

Programming Notes:

The effects of this instruction are identical to those accomplished by the sequence of reading *Status* into a GPR, setting the IE bit, and writing the result back to *Status*. Unlike the multiple instruction sequence, however, the EI instruction can not be aborted in the middle by an interrupt or exception.

This instruction creates an execution hazard between the change to the Status register and the point where the change to the interrupt enable takes effect. This hazard is cleared by the EHB, JALR.HB, JR.HB, or ERET instructions. Software must not assume that a fixed latency will clear the execution hazard.

| 31 | 26 25 | 24 6 | 5 | 0 |
|----------------|---------|------------------------------|----------------|---|
| COP0 010000 | CO 1 | 0 000 0000 0000 0000 0000 | ERET 011000 | |
| 6 | 1 | 19 | 6 | |

Format: ERET

Purpose: Exception Return

To return from interrupt, exception, or error trap.

Description:

ERET clears execution and instruction hazards, conditionally restores $\text{SRSCtl}_{\text{CSS}}$ from $\text{SRSCtl}_{\Pi\Sigma\Sigma}$ in a Release 2 implementation, and returns to the interrupted instruction at the completion of interrupt, exception, or error processing. ERET does not execute the next instruction (i.e., it has no delay slot).

Restrictions:

The operation of the processor is **UNDEFINED** if an ERET is executed in the delay slot of a branch or jump instruction.

An ERET placed between an LL and SC instruction will always cause the SC to fail.

ERET implements a software barrier that resolves all execution and instruction hazards created by Coprocessor 0 state changes (for Release 2 implementations, refer to the SYNCI instruction for additional information on resolving instruction hazards created by writing the instruction stream). The effects of this barrier are seen starting with the instruction fetch and decode of the instruction at the PC to which the ERET returns.

In a Release 2 implementation, ERET does not restore $SRSCtl_{CSS}$ from $SRSCtl_{PSS}$ if $Status_{BEV} = 1$, or if $Status_{ERL} = 1$ because any exception that sets $Status_{ERL}$ to 1 (Reset, Soft Reset, NMI, or cache error) does not save $SRSCtl_{CSS}$ in $SRSCtl_{PSS}$. If software sets $Status_{ERL}$ to 1, it must be aware of the operation of an ERET that may be subsequently executed.

Operation:

```
if Status_{ERL} = 1 then
     temp \leftarrow ErrorEPC
     Status_{ERL} \leftarrow 0
else
     temp \leftarrow EPC
     Status_{EXL} \leftarrow 0
     if (ArchitectureRevision \geq 2) and (SRSCtl<sub>HSS</sub> > 0) and (Status<sub>BEV</sub> = 0) then
          SRSCtl_{CSS} \leftarrow SRSCtl_{PSS}
     endif
endif
if IsMIPS16Implemented() | (Config3<sub>ISA</sub> > 0) then
     PC \leftarrow temp_{31..1} \mid \mid 0
     ISAMode \leftarrow \text{temp}_0
else
     PC \leftarrow temp
endif
LLbit \leftarrow 0
ClearHazards()
```

| | 6 | 5 | 5 | 5 | 5 | 6 | |

Format: EXT rt, rs, pos, size

Purpose: Extract Bit Field

To extract a bit field from GPR rs and store it right-justified into GPR rt.

Description: GPR[rt] ← ExtractField(GPR[rs], msbd, lsb)

The bit field starting at bit *pos* and extending for *size* bits is extracted from GPR *rs* and stored zero-extended and right-justified in GPR *rt*. The assembly language arguments *pos* and *size* are converted by the assembler to the instruction fields *msbd* (the most significant bit of the destination field in GPR *rt*), in instruction bits **15..11**, and *lsb* (least significant bit of the source field in GPR *rs*), in instruction bits **10..6**, as follows:

msbd \leftarrow size-1 lsb \leftarrow pos

The values of *pos* and *size* must satisfy all of the following relations:

0 ≤ pos < 32 0 < size ≤ 32 0 < pos+size ≤ 32

Figure 3-9 shows the symbolic operation of the instruction.

Restrictions:

In implementations prior to Release 2 of the architecture, this instruction resulted in a Reserved Instruction Exception.

The operation is **UNPREDICTABLE** if *lsb+msbd* > 31.

Operation:

Purpose: Floating Point Floor Convert to Long Fixed Point

To convert an FP value to 64-bit fixed point, rounding down

Description: FPR[fd] ← convert_and_round(FPR[fs])

The value in FPR *fs*, in format *fmt*, is converted to a value in 64-bit long fixed point format and rounded toward $-\infty$ (rounding mode 3). The result is placed in FPR *fd*.

When the source value is Infinity, NaN, or rounds to an integer outside the range -2^{63} to 2^{63} -1, the result cannot be represented correctly, an IEEE Invalid Operation condition exists, and the Invalid Operation flag is set in the *FCSR*. If the Invalid Operation Enable bit is set in the *FCSR*, no result is written to *fd* and an Invalid Operation exception is taken immediately. Otherwise, the default result, 2^{63} -1, is written to *fd*.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs—*fs* for type *fmt* and *fd* for long fixed point—if they are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fint*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of this instruction is **UNPREDICTABLE** if the processor is executing in 16 FP registers mode.

| 00 | J 0010 | | instr_index | |
| | 6 | 1 | 26 | |
| Form | at: Jta | arget | | MIPS32 |

Purpose: Jump

To branch within the current 256 MB-aligned region

Description:

This is a PC-region branch (not PC-relative); the effective target address is in the "current" 256 MB-aligned region. The low 28 bits of the target address is the *instr_index* field shifted left 2bits. The remaining upper bits are the corresponding bits of the address of the instruction in the delay slot (not the branch itself).

Jump to the effective target address. Execute the instruction that follows the jump, in the branch delay slot, before executing the jump itself.

Restrictions:

Processor operation is **UNPREDICTABLE** if a branch, jump, ERET, DERET, or WAIT instruction is placed in the delay slot of a branch or jump.

Operation:

I: I+1: PC \leftarrow PC_{GPRLEN-1..28} || instr_index || 0^2

Exceptions:

None

Programming Notes:

Forming the branch target address by catenating PC and index bits rather than adding a signed offset to the PC is an advantage if all program code addresses fit into a 256MB region aligned on a 256MB boundary. It allows a branch from anywhere in the region to anywhere in the region, an action not allowed by a signed relative offset.

This definition creates the following boundary case: When the jump instruction is in the last word of a 256MB region, it can branch only to the following 256MB region containing the branch delay slot.

Format: JAL target

Purpose: Jump and Link

To execute a procedure call within the current 256MB-aligned region

Description:

Place the return address link in GPR 31. The return link is the address of the second instruction following the branch, at which location execution continues after a procedure call.

This is a PC-region branch (not PC-relative); the effective target address is in the "current" 256MB-aligned region. The low 28 bits of the target address is the *instr_index* field shifted left 2bits. The remaining upper bits are the corresponding bits of the address of the instruction in the delay slot (not the branch itself).

Jump to the effective target address. Execute the instruction that follows the jump, in the branch delay slot, before executing the jump itself.

Restrictions:

Processor operation is **UNPREDICTABLE** if a branch, jump, ERET, DERET, or WAIT instruction is placed in the delay slot of a branch or jump.

Operation:

```
I: GPR[31] \leftarrow PC + 8
I+1: PC \leftarrow PC<sub>GPRLEN-1..28</sub> || instr_index || 0^2
```

Exceptions:

None

Programming Notes:

Forming the branch target address by catenating PC and index bits rather than adding a signed offset to the PC is an advantage if all program code addresses fit into a 256MB region aligned on a 256MB boundary. It allows a branch from anywhere in the region to anywhere in the region, an action not allowed by a signed relative offset.

This definition creates the following boundary case: When the branch instruction is in the last word of a 256MB region, it can branch only to the following 256MB region containing the branch delay slot.

MIPS32

| 31 | 26 | 25 21 | 20 16 | 15 11 | 10 6 | 5 0 | |
|----|-------------------|--------------------------|------------|-------|------|----------------|----------------|
| | SPECIAL 000000 | rs | 0 00000 | rd | hint | JALR 001001 | |
| | 6 | 5 | 5 | 5 | 5 | 6 | 1 |
|] | | rs (rd = 31 i: rd, rs | mplied) | | | | IPS32 IPS32 |

Purpose: Jump and Link Register

To execute a procedure call to an instruction address in a register

Description: GPR[rd] \leftarrow return_addr, PC \leftarrow GPR[rs]

Place the return address link in GPR *rd*. The return link is the address of the second instruction following the branch, where execution continues after a procedure call.

For processors that do not implement the MIPS16e ASE nor microMIPS32/64 ISA:

• Jump to the effective target address in GPR *rs*. Execute the instruction that follows the jump, in the branch delay slot, before executing the jump itself. Bit 0 of the target address is always zero so that no Address Exceptions occur when bit 0 of the source register is one.

For processors that do implement the MIPS16e ASE or microMIPS32/64 ISA:

• Jump to the effective target address in GPR *rs*. Execute the instruction that follows the jump, in the branch delay slot, before executing the jump itself. Set the *ISA Mode* bit to the value in GPR *rs* bit 0. Bit 0 of the target address is always zero so that no Address Exceptions occur when bit 0 of the source register is one.

In release 1 of the architecture, the only defined hint field value is 0, which sets default handling of JALR. In Release 2 of the architecture, bit 10 of the hint field is used to encode a hazard barrier. See the JALR.HB instruction description for additional information.

Restrictions:

Register specifiers *rs* and *rd* must not be equal, because such an instruction does not have the same effect when reexecuted. The result of executing such an instruction is **UNPREDICTABLE**. This restriction permits an exception handler to resume execution by re-executing the branch when an exception occurs in the branch delay slot.

If only one instruction set is implemented, then the effective target address must obey the alignment rules of the instruction set. If multiple instruction sets are implemented, the effective target address must obey the alignment rules of the intended instruction set of the target address as specified by the bit 0 or GPR *rs*.

For processors that do not implement the microMIPS32/64 ISA, the effective target address in GPR *rs* must be naturally-aligned. For processors that do not implement the MIPS16e ASE nor microMIPS32/64 ISA, if either of the two least-significant bits are not zero, an Address Error exception occurs when the branch target is subsequently fetched as an instruction.

For processors that do implement the MIPS16e ASE or microMIPS32/64 ISA, if target ISAMode bit is 0 (GPR *rs* bit 0) is zero and bit 1 is one, an Address Error exception occurs when the jump target is subsequently fetched as an instruction.

Processor operation is **UNPREDICTABLE** if a branch, jump, ERET, DERET, or WAIT instruction is placed in the delay slot of a branch or jump.

Operation:

I: temp ← GPR[rs]
 GPR[rd] ← PC + 8

| | | | HB rs (rd = 3 HB rd, rs | 1 implied) | | | | | | MIPS32 R MIPS32 R | |

Purpose: Jump and Link Register with Hazard Barrier

To execute a procedure call to an instruction address in a register and clear all execution and instruction hazards

Description: $GPR[rd] \leftarrow return_addr, PC \leftarrow GPR[rs], clear execution and instruction hazards$

Place the return address link in GPR *rd*. The return link is the address of the second instruction following the branch, where execution continues after a procedure call.

For processors that do not implement the MIPS16 ASE nor microMIPS32/64 ISA:

• Jump to the effective target address in GPR *rs*. Execute the instruction that follows the jump, in the branch delay slot, before executing the jump itself. Bit 0 of the target address is always zero so that no Address Exceptions occur when bit 0 of the source register is one.

For processors that do implement the MIPS16 ASE or microMIPS32/64 ISA:

• Jump to the effective target address in GPR *rs*. Execute the instruction that follows the jump, in the branch delay slot, before executing the jump itself. Set the *ISA Mode* bit to the value in GPR *rs* bit 0. Bit 0 of the target address is always zero so that no Address Exceptions occur when bit 0 of the source register is one.

JALR.HB implements a software barrier that resolves all execution and instruction hazards created by Coprocessor 0 state changes (for Release 2 implementations, refer to the SYNCI instruction for additional information on resolving instruction hazards created by writing the instruction stream). The effects of this barrier are seen starting with the instruction fetch and decode of the instruction at the PC to which the JALR.HB instruction jumps. An equivalent barrier is also implemented by the ERET instruction, but that instruction is only available if access to Coprocessor 0 is enabled, whereas JALR.HB is legal in all operating modes.

This instruction clears both execution and instruction hazards. Refer to the EHB instruction description for the method of clearing execution hazards alone.

JALR.HB uses bit 10 of the instruction (the upper bit of the hint field) to denote the hazard barrier operation.

Restrictions:

Register specifiers *rs* and *rd* must not be equal, because such an instruction does not have the same effect when reexecuted. The result of executing such an instruction is **UNPREDICTABLE**. This restriction permits an exception handler to resume execution by re-executing the branch when an exception occurs in the branch delay slot.

If only one instruction set is implemented, then the effective target address must obey the alignment rules of the instruction set. If multiple instruction sets are implemented, the effective target address must obey the alignment rules of the intended instruction set of the target address as specified by the bit 0 or GPR *rs*.

For processors that do not implement the microMIPS32/64 ISA, the effective target address in GPR *rs* must be naturally-aligned. For processors that do not implement the MIPS16 ASE nor microMIPS32/64 ISA, if either of the two least-significant bits are not zero, an Address Error exception occurs when the branch target is subsequently fetched as an instruction.

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

For processors that do implement the MIPS16 ASE or microMIPS32/64 ISA, if bit 0 is zero and bit 1 is one, an Address Error exception occurs when the jump target is subsequently fetched as an instruction.

After modifying an instruction stream mapping or writing to the instruction stream, execution of those instructions has **UNPREDICTABLE** behavior until the instruction hazard has been cleared with JALR.HB, JR.HB, ERET, or DERET. Further, the operation is **UNPREDICTABLE** if the mapping of the current instruction stream is modified.

JALR.HB does not clear hazards created by any instruction that is executed in the delay slot of the JALR.HB. Only hazards created by instructions executed before the JALR.HB are cleared by the JALR.HB.

Processor operation is **UNPREDICTABLE** if a branch, jump, ERET, DERET, or WAIT instruction is placed in the delay slot of a branch or jump.

Operation:

```
I: temp \leftarrow GPR[rs]
GPR[rd] \leftarrow PC + 8
I+1:if Config1<sub>CA</sub> = 0 then
PC \leftarrow temp
else
PC \leftarrow temp<sub>GPRLEN-1..1</sub> || 0
ISAMode \leftarrow temp<sub>0</sub>
endif
ClearHazards()
```

Exceptions:

None

Programming Notes:

This branch-and-link instruction can select a register for the return link; other link instructions use GPR 31. The default register for GPR *rd*, if omitted in the assembly language instruction, is GPR 31.

This instruction implements the final step in clearing execution and instruction hazards before execution continues. A hazard is created when a Coprocessor 0 or TLB write affects execution or the mapping of the instruction stream, or after a write to the instruction stream. When such a situation exists, software must explicitly indicate to hardware that the hazard should be cleared. Execution hazards alone can be cleared with the EHB instruction. Instruction hazards can only be cleared with a JR.HB, JALR.HB, or ERET instruction. These instructions cause hardware to clear the hazard before the instruction at the target of the jump is fetched. Note that because these instructions are encoded as jumps, the process of clearing an instruction hazard can often be included as part of a call (JALR) or return (JR) sequence, by simply replacing the original instructions with the HB equivalent.

Example: Clearing hazards due to an ASID change

```
/*
* Code used to modify ASID and call a routine with the new
* mapping established.
* a0 = New ASID to establish
 * a1 = Address of the routine to call
*/
        v0, C0_EntryHi /* Read current ASID */
v1, ~M_EntryHiASID /* Get negative mask for field */
   mfc0
   li
         v0, v0, v1 /* Clear out current ASID value */
   and
                             /* OR in new ASID value */
         v0, v0, a0
   or
   mtc0 v0, C0_EntryHi /* Rewrite EntryHi with new ASID */
                             /* Call routine, clearing the hazard */
   jalr.hb al
   nop
```

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

| 31 | 26 25 | (| 0 |
|----------------|-------|-------------|---|
| JALX 011101 | | instr_index | |
| 6 | · | 26 | |

Format: JALX target

MIPS32 with (microMIPS32 or MIPS16e)

Purpose: Jump and Link Exchange

To execute a procedure call within the current 256 MB-aligned region and change the *ISA Mode* from MIPS32 to microMIPS32 or MIPS16e.

Description:

Place the return address link in GPR 31. The return link is the address of the second instruction following the branch, at which location execution continues after a procedure call. The value stored in GPR 31 bit 0 reflects the current value of the *ISA Mode* bit.

This is a PC-region branch (not PC-relative); the effective target address is in the "current" 256 MB-aligned region. The low 28 bits of the target address is the *instr_index* field shifted left 2 bits. The remaining upper bits are the corresponding bits of the address of the instruction in the delay slot (not the branch itself).

Jump to the effective target address, toggling the *ISA Mode* bit. Execute the instruction that follows the jump, in the branch delay slot, before executing the jump itself.

Restrictions:

This instruction only supports 32-bit aligned branch target addresses.

Processor operation is **UNPREDICTABLE** if a branch, jump, ERET, DERET, or WAIT instruction is placed in the delay slot of a branch or jump.

If the microMIPS base architecture is not implemented and the MIPS16e ASE is not implemented, a Reserved Instruction Exception is initiated.

Operation:

```
I: GPR[31] \leftarrow PC + 8

I+1: PC \leftarrow PC<sub>GPRLEN-1..28</sub> || instr_index || 0<sup>2</sup>

ISAMode \leftarrow (not ISAMode)
```

Exceptions:

None

Programming Notes:

Forming the branch target address by concatenating PC and index bits rather than adding a signed offset to the PC is an advantage if all program code addresses fit into a 256 MB region aligned on a 256 MB boundary. It allows a branch from anywhere in the region to anywhere in the region, an action not allowed by a signed relative offset.

This definition creates the following boundary case: When the branch instruction is in the last word of a 256 MB region, it can branch only to the following 256 MB region containing the branch delay slot.

| 31 | 26 | 25 21 | 20 11 | 10 6 | 5 0 | |
|----|-------------------|-------|-------------------|------|--------------|--|
| | SPECIAL 000000 | rs | 0 00 0000 0000 | hint | JR 001000 | |
| | 6 | 5 | 10 | 5 | 6 | |

Format: JR rs

Purpose: Jump Register

To execute a branch to an instruction address in a register

Description: PC ← GPR[rs]

Jump to the effective target address in GPR *rs*. Execute the instruction following the jump, in the branch delay slot, before jumping.

For processors that implement the MIPS16e ASE or microMIPS32/64 ISA, set the *ISA Mode* bit to the value in GPR *rs* bit 0. Bit 0 of the target address is always zero so that no Address Exceptions occur when bit 0 of the source register is one

Restrictions:

If only one instruction set is implemented, then the effective target address must obey the alignment rules of the instruction set. If multiple instruction sets are implemented, the effective target address must obey the alignment rules of the intended instruction set of the target address as specified by the bit 0 or GPR *rs*.

For processors that do not implement the microMIPS ISA, the effective target address in GPR *rs* must be naturallyaligned. For processors that do not implement the MIPS16e ASE or microMIPS ISA, if either of the two least-significant bits are not zero, an Address Error exception occurs when the branch target is subsequently fetched as an instruction.

For processors that do implement the MIPS16e ASE or microMIPS ISA, if bit 0 is zero and bit 1 is one, an Address Error exception occurs when the jump target is subsequently fetched as an instruction.

In release 1 of the architecture, the only defined hint field value is 0, which sets default handling of JR. In Release 2 of the architecture, bit 10 of the hint field is used to encode an instruction hazard barrier. See the JR.HB instruction description for additional information.

Processor operation is **UNPREDICTABLE** if a branch, jump, ERET, DERET, or WAIT instruction is placed in the delay slot of a branch or jump.

Operation:

```
I: temp \leftarrow GPR[rs]
I+1:if Config1<sub>CA</sub> = 0 then
        PC \leftarrow temp
else
        PC \leftarrow temp<sub>GPRLEN-1..1</sub> || 0
        ISAMode \leftarrow temp<sub>0</sub>
endif
```

Exceptions:

None

Programming Notes:

Software should use the value 31 for the *rs* field of the instruction word on return from a JAL, JALR, or BGEZAL, and should use a value other than 31 for remaining uses of JR.

| | 6 | | 5 | | 10 | | 1 | 4 | | 6 | |

Format: JR.HB rs

Purpose: Jump Register with Hazard Barrier

To execute a branch to an instruction address in a register and clear all execution and instruction hazards.

Description: PC \leftarrow GPR[rs], clear execution and instruction hazards

Jump to the effective target address in GPR *rs*. Execute the instruction following the jump, in the branch delay slot, before jumping.

JR.HB implements a software barrier that resolves all execution and instruction hazards created by Coprocessor 0 state changes (for Release 2 implementations, refer to the SYNCI instruction for additional information on resolving instruction hazards created by writing the instruction stream). The effects of this barrier are seen starting with the instruction fetch and decode of the instruction at the PC to which the JR.HB instruction jumps. An equivalent barrier is also implemented by the ERET instruction, but that instruction is only available if access to Coprocessor 0 is enabled, whereas JR.HB is legal in all operating modes.

This instruction clears both execution and instruction hazards. Refer to the EHB instruction description for the method of clearing execution hazards alone.

JR.HB uses bit 10 of the instruction (the upper bit of the hint field) to denote the hazard barrier operation.

For processors that implement the MIPS16e ASE or microMIPS32/64 ISA, set the *ISA Mode* bit to the value in GPR *rs* bit 0. Bit 0 of the target address is always zero so that no Address Exceptions occur when bit 0 of the source register is one.

Restrictions:

If only one instruction set is implemented, then the effective target address must obey the alignment rules of the instruction set. If multiple instruction sets are implemented, the effective target address must obey the alignment rules of the intended instruction set of the target address as specified by the bit 0 or GPR *rs*.

For processors that do not implement the microMIPS ISA, the effective target address in GPR *rs* must be naturallyaligned. For processors that do not implement the MIPS16 ASE or microMIPS ISA, if either of the two least-significant bits are not zero, an Address Error exception occurs when the branch target is subsequently fetched as an instruction.

For processors that do implement the MIPS16 ASE or microMIPS ISA, if bit 0 is zero and bit 1 is one, an Address Error exception occurs when the jump target is subsequently fetched as an instruction.

After modifying an instruction stream mapping or writing to the instruction stream, execution of those instructions has **UNPREDICTABLE** behavior until the hazard has been cleared with JALR.HB, JR.HB, ERET, or DERET. Further, the operation is **UNPREDICTABLE** if the mapping of the current instruction stream is modified.

JR.HB does not clear hazards created by any instruction that is executed in the delay slot of the JR.HB. Only hazards created by instructions executed before the JR.HB are cleared by the JR.HB.

Processor operation is **UNPREDICTABLE** if a branch, jump, ERET, DERET, or WAIT instruction is placed in the delay slot of a branch or jump.

Operation:

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

| 31 | 26 25 2 | 1 20 16 | 15 0 |
|--------------|---------|---------|--------|
| LL 110000 | base | rt | offset |
| 6 | 5 | 5 | 16 |

Format: LL rt, offset(base)

Purpose: Load Linked Word

To load a word from memory for an atomic read-modify-write

Description: GPR[rt] ← memory[GPR[base] + offset]

The LL and SC instructions provide the primitives to implement atomic read-modify-write (RMW) operations for synchronizable memory locations.

The contents of the 32-bit word at the memory location specified by the aligned effective address are fetched and written into GPR *rt*. The 16-bit signed *offset* is added to the contents of GPR *base* to form an effective address.

This begins a RMW sequence on the current processor. There can be only one active RMW sequence per processor. When an LL is executed it starts an active RMW sequence replacing any other sequence that was active. The RMW sequence is completed by a subsequent SC instruction that either completes the RMW sequence atomically and succeeds, or does not and fails.

Executing LL on one processor does not cause an action that, by itself, causes an SC for the same block to fail on another processor.

An execution of LL does not have to be followed by execution of SC; a program is free to abandon the RMW sequence without attempting a write.

Restrictions:

The addressed location must be synchronizable by all processors and I/O devices sharing the location; if it is not, the result is **UNPREDICTABLE**. Which storage is synchronizable is a function of both CPU and system implementations. See the documentation of the SC instruction for the formal definition.

The effective address must be naturally-aligned. If either of the 2 least-significant bits of the effective address is non-zero, an Address Error exception occurs.

Operation:

```
vAddr ← sign_extend(offset) + GPR[base]
if vAddr<sub>1..0</sub> ≠ 0<sup>2</sup> then
    SignalException(AddressError)
endif
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, LOAD)
memword ← LoadMemory (CCA, WORD, pAddr, vAddr, DATA)

| LWL 100010 | base | rt | offset | |
| 6 | 5 | 5 | 16 | |
| Format: LWL | rt, offset(bas | e) | | MIPS32 |

Purpose: Load Word Left

To load the most-significant part of a word as a signed value from an unaligned memory address

Description: GPR[rt] ← GPR[rt] MERGE memory[GPR[base] + offset]

The 16-bit signed *offset* is added to the contents of GPR *base* to form an effective address (*EffAddr*). *EffAddr* is the address of the most-significant of 4 consecutive bytes forming a word (W) in memory starting at an arbitrary byte boundary.

The most-significant 1 to 4 bytes of W is in the aligned word containing the *EffAddr*. This part of W is loaded into the most-significant (left) part of the word in GPR rt. The remaining least-significant part of the word in GPR rt is unchanged.

The figure below illustrates this operation using big-endian byte ordering for 32-bit and 64-bit registers. The 4 consecutive bytes in 2...5 form an unaligned word starting at location 2. A part of W, 2 bytes, is in the aligned word containing the most-significant byte at 2. First, LWL loads these 2 bytes into the left part of the destination register word and leaves the right part of the destination word unchanged. Next, the complementary LWR loads the remainder of the unaligned word

The bytes loaded from memory to the destination register depend on both the offset of the effective address within an aligned word, that is, the low 2 bits of the address (vAddr_{1.0}), and the current byte-ordering mode of the processor (big- or little-endian). The figure below shows the bytes loaded for every combination of offset and byte ordering.

```

Exceptions:

None

TLB Refill, TLB Invalid, Bus Error, Address Error, Watch

Programming Notes:

The architecture provides no direct support for treating unaligned words as unsigned values, that is, zeroing bits 63..32 of the destination register when bit 31 is loaded.

Historical Information:

In the MIPS I architecture, the LWL and LWR instructions were exceptions to the load-delay scheduling restriction. A LWL or LWR instruction which was immediately followed by another LWL or LWR instruction, and used the same destination register would correctly merge the 1 to 4 loaded bytes with the data loaded by the previous instruction. All such restrictions were removed from the architecture in MIPS II.

| LWR 100110 | base | rt | offset | |
| 6 | 5 | 5 | 16 | |
| Format: LWR | rt, offset(bas | e) | | MIPS32 |

Purpose: Load Word Right

To load the least-significant part of a word from an unaligned memory address as a signed value

Description: GPR[rt] ← GPR[rt] MERGE memory[GPR[base] + offset]

The 16-bit signed *offset* is added to the contents of GPR *base* to form an effective address (*EffAddr*). *EffAddr* is the address of the least-significant of 4 consecutive bytes forming a word (W) in memory starting at an arbitrary byte boundary.

A part of *W*, the least-significant 1 to 4 bytes, is in the aligned word containing *EffAddr*. This part of *W* is loaded into the least-significant (right) part of the word in GPR *rt*. The remaining most-significant part of the word in GPR *rt* is unchanged.

Executing both LWR and LWL, in either order, delivers a sign-extended word value in the destination register.

The figure below illustrates this operation using big-endian byte ordering for 32-bit and 64-bit registers. The 4 consecutive bytes in 2..5 form an unaligned word starting at location 2. A part of *W*, 2 bytes, is in the aligned word containing the least-significant byte at 5. First, LWR loads these 2 bytes into the right part of the destination register. Next, the complementary LWL loads the remainder of the unaligned word.

Figure 3.7 Unaligned Word Load Using LWL and LWR

The bytes loaded from memory to the destination register depend on both the offset of the effective address within an aligned word, that is, the low 2 bits of the address (vAddr_{1..0}), and the current byte-ordering mode of the processor (big- or little-endian). The figure below shows the bytes loaded for every combination of offset and byte ordering.

Figure 3.8 Bytes Loaded by LWR Instruction

Restrictions:

None

Operation:

Exceptions:

TLB Refill, TLB Invalid, Bus Error, Address Error, Watch

Programming Notes:

The architecture provides no direct support for treating unaligned words as unsigned values, that is, zeroing bits 63..32 of the destination register when bit 31 is loaded.

Historical Information:

In the MIPS I architecture, the LWL and LWR instructions were exceptions to the load-delay scheduling restriction. A LWL or LWR instruction which was immediately followed by another LWL or LWR instruction, and used the same destination register would correctly merge the 1 to 4 loaded bytes with the data loaded by the previous instruction. All such restrictions were removed from the architecture in MIPS II.

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

| | 6 | 5 | | 5 | | 5 | | 5 | | | 6 | _ |

Format: MADD rs, rt

Purpose: Multiply and Add Word to Hi,Lo

To multiply two words and add the result to Hi, Lo

Description: (HI,LO) \leftarrow (HI,LO) + (GPR[rs] \times GPR[rt])

The 32-bit word value in GPR rs is multiplied by the 32-bit word value in GPR rt, treating both operands as signed values, to produce a 64-bit result. The product is added to the 64-bit concatenated values of H/ and LO. The most significant 32 bits of the result are written into H/ and the least significant 32 bits are written into LO. No arithmetic exception occurs under any circumstances.

Restrictions:

None

This instruction does not provide the capability of writing directly to a target GPR.

Operation:

```
\begin{array}{l} \text{temp} \leftarrow (\text{HI} \mid \mid \text{LO}) + (\text{GPR[rs]} \times \text{GPR[rt]}) \\ \text{HI} \leftarrow \text{temp}_{63..32} \\ \text{LO} \leftarrow \text{temp}_{31..0} \end{array}
```

Exceptions:

None

Programming Notes:

Where the size of the operands are known, software should place the shorter operand in GPR *rt*. This may reduce the latency of the instruction on those processors which implement data-dependent instruction latencies.

| 31 | 26 | 25 | 21 20 | 16 | 15 11 | 10 | 6 | 5 | 3 | 2 | 0 |
|----------------|-------|---|-------|----|-------|----|---|-------------|------|----------|-------------------------------------|

| 6 | | 5 | 1 | 5 | 5 | 5 | | 3 | | 3 | |
| Format: | MADD. | fmt S fd, fr, f D fd, fr, f PS fd, fr, | s, ft | | | | | MIPS64 | 1, N | 1IPS32 R | Kelease 2 Kelease 2 Kelease 2 |

Purpose: Floating Point Multiply Add

To perform a combined multiply-then-add of FP values

Description: FPR[fd] ← (FPR[fs] × FPR[ft]) + FPR[fr]

The value in FPR fs is multiplied by the value in FPR ft to produce an intermediate product. The intermediate product is rounded according to the current rounding mode in *FCSR*. The value in FPR fr is added to the product. The result sum is calculated to infinite precision, rounded according to the current rounding mode in *FCSR*, and placed into FPR fd. The operands and result are values in format *fmt*. The results and flags are as if separate floating-point multiply and add instructions were executed.

MADD.PS multiplies then adds the upper and lower halves of FPR *fr*, FPR *fs*, and FPR *ft* independently, and ORs together any generated exceptional conditions.

Cause bits are ORed into the Flag bits if no exception is taken.

Restrictions:

The fields *fr*, *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *fmt*; if they are not valid, the result is **UNPREDICTABLE**.

The operands must be values in format *fmt*; if they are not, the result is **UNPREDICTABLE** and the value of the operand FPRs becomes **UNPREDICTABLE**.

The result of MADD.PS is UNPREDICTABLE if the processor is executing in 16 FP registers mode.

Operation:

```
\begin{split} \text{vfr} &\leftarrow \text{ValueFPR(fr, fmt)} \\ \text{vfs} &\leftarrow \text{ValueFPR(fs, fmt)} \\ \text{vft} &\leftarrow \text{ValueFPR(ft, fmt)} \\ \text{StoreFPR(fd, fmt, (vfs $\times_{fmt}$ vft) $+_{fmt}$ vfr)} \end{split}
```

To move the contents of a coprocessor 0 register to a general register.

Description: GPR[rt] ← CPR[0,rd,sel]

The contents of the coprocessor 0 register specified by the combination of *rd* and *sel* are loaded into general register *rt*. Note that not all coprocessor 0 registers support the *sel* field. In those instances, the *sel* field must be zero.

Restrictions:

The results are **UNDEFINED** if coprocessor 0 does not contain a register as specified by *rd* and *sel*.

Operation:

data \leftarrow CPR[0,rd,sel] GPR[rt] \leftarrow data

Exceptions:

Coprocessor Unusable

Reserved Instruction

| | 6 | 5 | 5 | 5 | 11 | |

Format: MFC1 rt, fs

Purpose: Move Word From Floating Point

To copy a word from an FPU (CP1) general register to a GPR

Description: GPR[rt] ← FPR[fs]

The contents of FPR fs are loaded into general register rt.

Restrictions:

Operation:

data \leftarrow ValueFPR(fs, UNINTERPRETED_WORD) GPR[rt] \leftarrow data

Exceptions:

Coprocessor Unusable, Reserved Instruction

Historical Information:

For MIPS I, MIPS II, and MIPS III the contents of GPR *rt* are **UNPREDICTABLE** for the instruction immediately following MFC1.

| | Format: | | rt, Impl rt, Impl | , se | 1 | | | | | | | | IPS32 IPS32 |

The syntax shown above is an example using MFC1 as a model. The specific syntax is implementation dependent.

Purpose: Move Word From Coprocessor 2

To copy a word from a COP2 general register to a GPR

Description: GPR[rt] ← CP2CPR[Impl]

The contents of the coprocessor 2 register denoted by the *lmpl* field are and placed into general register *rt*. The interpretation of the *lmpl* field is left entirely to the Coprocessor 2 implementation and is not specified by the architecture.

Restrictions:

The results are UNPREDICTABLE if Impl specifies a coprocessor 2 register that does not exist.

Operation:

```
data \leftarrow CP2CPR[Impl]
GPR[rt] \leftarrow data
```

Exceptions:

Coprocessor Unusable

| 6 | | 5 | | 5 | | | 5 | | | 11 | |

Format: MFHC1 rt, fs

Purpose: Move Word From High Half of Floating Point Register

To copy a word from the high half of an FPU (CP1) general register to a GPR

Description: GPR[rt] ← FPR[fs]_{63..32}

The contents of the high word of FPR *fs* are loaded into general register *rt*. This instruction is primarily intended to support 64-bit floating point units on a 32-bit CPU, but the semantics of the instruction are defined for all cases.

Restrictions:

In implementations prior to Release 2 of the architecture, this instruction resulted in a Reserved Instruction Exception.

The results are **UNPREDICTABLE** if Status_{FR} = 0 and *fs* is odd.

Operation:

```
data \leftarrow ValueFPR(fs, UNINTERPRETED_DOUBLEWORD)<sub>63..32</sub>
GPR[rt] \leftarrow data
```

Exceptions:

Coprocessor Unusable

Reserved Instruction

| | | |) fd, fs PS fd, f | | | | | | | | Μ | IPS64, MIPS32 | MIPS32 Release 2 |

Purpose: Floating Point Move

To move an FP value between FPRs

Description: FPR[fd] ← FPR[fs]

The value in FPR fs is placed into FPR fd. The source and destination are values in format fmt. In paired-single format, both the halves of the pair are copied to fd.

The move is non-arithmetic; it causes no IEEE 754 exceptions.

Restrictions:

The fields fs and fd must specify FPRs valid for operands of type fmt; if they are not valid, the result is UNPRE-DICTABLE.

The operand must be a value in format *fmt*; if it is not, the result is UNPREDICTABLE and the value of the operand FPR becomes UNPREDICTABLE.

The result of MOV.PS is **UNPREDICTABLE** if the processor is executing in 16 FP registers mode.

Operation:

```
StoreFPR(fd, fmt, ValueFPR(fs, fmt))
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Unimplemented Operation

| Format: | MOVF. MOVF. | fmt S fd, fs, cc D fd, fs, cc PS fd, fs, c | | | | | | | | MIPS32 | MIPS32 MIPS32 MIPS64 2 Release 2 |

Purpose: Floating Point Move Conditional on Floating Point False

To test an FP condition code then conditionally move an FP value

Description: if FPConditionCode(cc) = 0 then FPR[fd] ← FPR[fs]

If the floating point condition code specified by *CC* is zero, then the value in FPR *fs* is placed into FPR *fd*. The source and destination are values in format *fmt*.

If the condition code is not zero, then FPR *fs* is not copied and FPR *fd* retains its previous value in format *fmt*. If *fd* did not contain a value either in format *fmt* or previously unused data from a load or move-to operation that could be interpreted in format *fmt*, then the value of *fd* becomes **UNPREDICTABLE**.

MOVF.PS conditionally merges the lower half of FPR fs into the lower half of FPR fd if condition code CC is zero, and independently merges the upper half of FPR fs into the upper half of FPR fd if condition code CC+1 is zero. The CC field must be even; if it is odd, the result of this operation is **UNPREDICTABLE**.

The move is non-arithmetic; it causes no IEEE 754 exceptions.

Restrictions:

The fields *fs* and *fd* must specify FPRs valid for operands of type *fint*; if they are not valid, the result is **UNPRE-DICTABLE**. The operand must be a value in format *fint*; if it is not, the result is **UNPREDITABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of MOVF.PS is UNPREDICTABLE if the processor is executing in 16 FP registers mode.

Operation:

```
if FPConditionCode(cc) = 0 then
   StoreFPR(fd, fmt, ValueFPR(fs, fmt))
else
   StoreFPR(fd, fmt, ValueFPR(fd, fmt))
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

| | 6 | 5 | 5 | 5 | 5 | 6 |

Format: MSUB rs, rt

Purpose: Multiply and Subtract Word to Hi,Lo

To multiply two words and subtract the result from HI, LO

Description: (HI,LO) \leftarrow (HI,LO) - (GPR[rs] \times GPR[rt])

The 32-bit word value in GPR rs is multiplied by the 32-bit value in GPR rt, treating both operands as signed values, to produce a 64-bit result. The product is subtracted from the 64-bit concatenated values of H/ and LO. The most significant 32 bits of the result are written into H/ and the least significant 32 bits are written into LO. No arithmetic exception occurs under any circumstances.

Restrictions:

None

This instruction does not provide the capability of writing directly to a target GPR.

Operation:

```
\begin{array}{l} \text{temp} \leftarrow (\text{HI} \mid \mid \text{LO}) - (\text{GPR[rs]} \times \text{GPR[rt]}) \\ \text{HI} \leftarrow \text{temp}_{63..32} \\ \text{LO} \leftarrow \text{temp}_{31..0} \end{array}
```

Exceptions:

None

Programming Notes:

Where the size of the operands are known, software should place the shorter operand in GPR *rt*. This may reduce the latency of the instruction on those processors which implement data-dependent instruction latencies.

Purpose: Floating Point Multiply Subtract

To perform a combined multiply-then-subtract of FP values

Description: FPR[fd] ← (FPR[fs] × FPR[ft]) - FPR[fr]

The value in FPR *fs* is multiplied by the value in FPR *ft* to produce an intermediate product. The intermediate product is rounded according to the current rounding mode in *FCSR*. The value in FPR *fr* is subtracted from the product. The subtraction result is calculated to infinite precision, rounded according to the current rounding mode in *FCSR*, and placed into FPR *fd*. The operands and result are values in format *fmt*. The results and flags are as if separate floating-point multiply and subtract instructions were executed.

MSUB.PS multiplies then subtracts the upper and lower halves of FPR *fr*, FPR *fs*, and FPR *ft* independently, and ORs together any generated exceptional conditions.

Cause bits are ORed into the Flag bits if no exception is taken.

Restrictions:

The fields *fr*, *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *fmt*; if they are not valid, the result is **UNPREDICTABLE**.

The operands must be values in format *fmt*; if they are not, the result is **UNPREDICTABLE** and the value of the operand FPRs becomes **UNPREDICTABLE**.

The result of MSUB.PS is UNPREDICTABLE if the processor is executing in 16 FP registers mode.

Operation:

```
\begin{split} \text{vfr} &\leftarrow \text{ValueFPR}(\text{fr, fmt}) \\ \text{vfs} &\leftarrow \text{ValueFPR}(\text{fs, fmt}) \\ \text{vft} &\leftarrow \text{ValueFPR}(\text{ft, fmt}) \\ \text{StoreFPR}(\text{fd, fmt, (vfs} \times_{\text{fmt}} \text{vft}) -_{\text{fmt}} \text{vfr})) \end{split}
```

Exceptions:

| | 6 | 5 | 5 | 5 | 8 | 3 | 1 |
| | Format: MTC0 MTC0 | rt, rd rt, rd, sel | | | | | IPS32 IPS32 |

Purpose: Move to Coprocessor 0

To move the contents of a general register to a coprocessor 0 register.

Description: CPR[0, rd, sel] ← GPR[rt]

The contents of general register rt are loaded into the coprocessor 0 register specified by the combination of *rd* and *sel*. Not all coprocessor 0 registers support the the *sel* field. In those instances, the *sel* field must be set to zero.

Restrictions:

The results are **UNDEFINED** if coprocessor 0 does not contain a register as specified by *rd* and *sel*.

Operation:

data ← GPR[rt]
CPR[0,rd,sel] ← data

Exceptions:

Coprocessor Unusable

Reserved Instruction

| 31 | 26 | 25 | 21 | 20 | 16 | 15 | | 11 | 10 | 0 |

| 6 | | 5 | | 5 | | | 5 | | 11 | |

Format: MTC1 rt, fs

Purpose: Move Word to Floating Point

To copy a word from a GPR to an FPU (CP1) general register

Description: FPR[fs] ← GPR[rt]

The low word in GPR rt is placed into the low word of FPR fs.

Restrictions:

Operation:

```
data \leftarrow GPR[rt]<sub>31..0</sub>
StoreFPR(fs, UNINTERPRETED_WORD, data)
```

Exceptions:

Coprocessor Unusable

Historical Information:

For MIPS I, MIPS II, and MIPS III the value of FPR *fs* is **UNPREDICTABLE** for the instruction immediately following MTC1.

| 3 | 1 | 26 | 25 | 21 | 20 | 16 | 15 | 11 | I 10 | 8 | 7 | 0 | |
|---|----------------|----|--------------------|----------|----|----|----|----|------|----|----|------|--|

| | 6 | | ŧ | 5 | 5 | | | | | 1 | 6 | | |
| | Format: M | | rt, Imp rt, Imp | | | | | | | | | MIPS | |

The syntax shown above is an example using MTC1 as a model. The specific syntax is implementation dependent.

Purpose: Move Word to Coprocessor 2

To copy a word from a GPR to a COP2 general register

Description: CP2CPR[Impl] ← GPR[rt]

The low word in GPR *rt* is placed into the low word of coprocessor 2 general register denoted by the *lmpl* field. The interpretation of the *lmpl* field is left entirely to the Coprocessor 2 implementation and is not specified by the architecture.

Restrictions:

The results are UNPREDICTABLE if *Impl* specifies a coprocessor 2 register that does not exist.

Operation:

```
data \leftarrow GPR[rt]
CP2CPR[Impl] \leftarrow data
```

Exceptions:

Coprocessor Unusable

Reserved Instruction

| 31 | 26 | 25 | 21 | 20 | 16 | 15 | | 11 | 10 | 0 |
|----------------|----|--------------|----|----|----|----|----|----|----|--------------------|
| COP1 010001 | | MTH 00111 | | rt | ţ | | fs | | | 0 000 0000 0000 |
| 6 | | 5 | | 5 | | | 5 | | | 11 |

Format: MTHC1 rt, fs

Purpose: Move Word to High Half of Floating Point Register

To copy a word from a GPR to the high half of an FPU (CP1) general register

Description: FPR[fs]_{63..32} ← GPR[rt]

The word in GPR *rt* is placed into the high word of FPR *fs*. This instruction is primarily intended to support 64-bit floating point units on a 32-bit CPU, but the semantics of the instruction are defined for all cases.

Restrictions:

In implementations prior to Release 2 of the architecture, this instruction resulted in a Reserved Instruction Exception.

The results are **UNPREDICTABLE** if Status_{FR} = 0 and *fs* is odd.

Operation:

```
\label{eq:constraint} \begin{array}{l} \texttt{newdata} \leftarrow \texttt{GPR[rt]olddata} \leftarrow \texttt{ValueFPR(fs, UNINTERPRETED_DOUBLEWORD)}_{31..0} \\ \texttt{StoreFPR(fs, UNINTERPRETED_DOUBLEWORD, newdata} \mid \mid \texttt{olddata}) \end{array}
```

Exceptions:

Coprocessor Unusable

Reserved Instruction

Programming Notes

When paired with MTC1 to write a value to a 64-bit FPR, the MTC1 must be executed first, followed by the MTHC1. This is because of the semantic definition of MTC1, which is not aware that software will be using an MTHC1 instruction to complete the operation, and sets the upper half of the 64-bit FPR to an **UNPREDICTABLE** value.

MIPS32 Release 2

| 3 | 26 | 6 25 | 21 20 | 16 15 | 5 11 10 | 0 |
|---|----------------------|---------------------------|-------|-------|---------|--------------------------------------|

| | 6 | 5 | 5 | 1 | 16 | |
| | Format: MTHC MTHC | 2 rt, Impl 2 rt, Impl, | sel | | | MIPS32 Release 2 MIPS32 Release 2 |

The syntax shown above is an example using MTHC1 as a model. The specific syntax is implementation dependent.

Purpose: Move Word to High Half of Coprocessor 2 Register

To copy a word from a GPR to the high half of a COP2 general register

Description: CP2CPR[Impl]_{63..32} ← GPR[rt]

The word in GPR *rt* is placed into the high word of coprocessor 2 general register denoted by the *lmpl* field. The interpretation of the *lmpl* field is left entirely to the Coprocessor 2 implementation and is not specified by the architecture.

Restrictions:

The results are **UNPREDICTABLE** if *Impl* specifies a coprocessor 2 register that does not exist, or if that register is not 64 bits wide.

In implementations prior to Release 2 of the architecture, this instruction resulted in a Reserved Instruction Exception.

Operation:

```
data \leftarrow GPR[rt]
CP2CPR[Impl] \leftarrow data || CPR[2,rd,sel]<sub>31..0</sub>
```

Exceptions:

Coprocessor Unusable

Reserved Instruction

Programming Notes

When paired with MTC2 to write a value to a 64-bit CPR, the MTC2 must be executed first, followed by the MTHC2. This is because of the semantic definition of MTC2, which is not aware that software will be using an MTHC2 instruction to complete the operation, and sets the upper half of the 64-bit CPR to an **UNPREDICTABLE** value.

| 31 | 26 | 25 21 | 20 6 | 5 0 | D |
|-------------------|----|-------|-------------------------|----------------|---|
| SPECIAI 000000 | | rs | 0 000 0000 0000 0000 | MTHI 010001 | |
| 6 | | 5 | 15 | 6 | |

Format: MTHI rs

Purpose: Move to HI Register

To copy a GPR to the special purpose HI register

Description: HI ← GPR[rs]

The contents of GPR rs are loaded into special register Hl.

Restrictions:

A computed result written to the H//LO pair by DIV, DIVU, MULT, or MULTU must be read by MFHI or MFLO before a new result can be written into either H/ or LO.

If an MTHI instruction is executed following one of these arithmetic instructions, but before an MFLO or MFHI instruction, the contents of *LO* are **UNPREDICTABLE**. The following example shows this illegal situation:

```
MULT r2,r4 # start operation that will eventually write to HI,L0
... # code not containing mfhi or mflo
MTHI r6
... # code not containing mflo
MFLO r3 # this mflo would get an UNPREDICTABLE value
```

Operation:

 $HI \leftarrow GPR[rs]$

Exceptions:

None

Historical Information:

In MIPS I-III, if either of the two preceding instructions is MFHI, the result of that MFHI is **UNPREDICTABLE**. Reads of the *HI* or *LO* special register must be separated from any subsequent instructions that write to them by two or more instructions. In MIPS IV and later, including MIPS32 and MIPS64, this restriction does not exist.

| | 6 | 5 | 15 | 6 | |

Format: MTLO rs

Purpose: Move to LO Register

To copy a GPR to the special purpose LO register

Description: LO ← GPR[rs]

The contents of GPR rs are loaded into special register LO.

Restrictions:

A computed result written to the H/LO pair by DIV, DIVU, MULT, or MULTU must be read by MFHI or MFLO before a new result can be written into either H/ or LO.

If an MTLO instruction is executed following one of these arithmetic instructions, but before an MFLO or MFHI instruction, the contents of *H*/ are **UNPREDICTABLE**. The following example shows this illegal situation:

```
MULT r2,r4 # start operation that will eventually write to HI,L0
... # code not containing mfhi or mflo
MTLO r6
... # code not containing mfhi
MFHI r3 # this mfhi would get an UNPREDICTABLE value
```

Operation:

 $LO \leftarrow GPR[rs]$

Exceptions:

None

Historical Information:

In MIPS I-III, if either of the two preceding instructions is MFHI, the result of that MFHI is **UNPREDICTABLE**. Reads of the *HI* or *LO* special register must be separated from any subsequent instructions that write to them by two or more instructions. In MIPS IV and later, including MIPS32 and MIPS64, this restriction does not exist.

| 31 | 26 | 25 | 21 | 20 1 | 6 | 15 | 11 | 10 | 6 | 5 | 0 |
|----|--------------------|----|----|------|---|----|----|------------|---|---------------|---|
| | SPECIAL2 011100 | rs | | rt | | rd | | 0 00000 | | MUL 000010 | |
| | 6 | 5 | | 5 | | 5 | | 5 | | 6 | |

Format: MUL rd, rs, rt

Purpose: Multiply Word to GPR

To multiply two words and write the result to a GPR.

Description: GPR[rd] ← GPR[rs] × GPR[rt]

The 32-bit word value in GPR rs is multiplied by the 32-bit value in GPR rt, treating both operands as signed values, to produce a 64-bit result. The least significant 32 bits of the product are written to GPR rd. The contents of Hl and LO are **UNPREDICTABLE** after the operation. No arithmetic exception occurs under any circumstances.

Restrictions:

Note that this instruction does not provide the capability of writing the result to the H and LO registers.

Operation:

```
temp \leftarrow GPR[rs] × GPR[rt]
GPR[rd] \leftarrow temp<sub>31..0</sub>
HI \leftarrow UNPREDICTABLE
LO \leftarrow UNPREDICTABLE
```

Exceptions:

None

Programming Notes:

In some processors the integer multiply operation may proceed asynchronously and allow other CPU instructions to execute before it is complete. An attempt to read GPR *rd* before the results are written interlocks until the results are ready. Asynchronous execution does not affect the program result, but offers an opportunity for performance improvement by scheduling the multiply so that other instructions can execute in parallel.

Programs that require overflow detection must check for it explicitly.

Where the size of the operands are known, software should place the shorter operand in GPR *rt*. This may reduce the latency of the instruction on those processors which implement data-dependent instruction latencies.

| | | | | | | MIPS32 Release 2 |
| | | | | | | |

Purpose: Floating Point Multiply

To multiply FP values

Description: FPR[fd] ← FPR[fs] × FPR[ft]

The value in FPR *fs* is multiplied by the value in FPR *ft*. The result is calculated to infinite precision, rounded according to the current rounding mode in *FCSR*, and placed into FPR *fd*. The operands and result are values in format *fmt*. MUL.PS multiplies the upper and lower halves of FPR *fs* and FPR *ft* independently, and ORs together any generated exceptional conditions.

Restrictions:

The fields *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *fmt*; if they are not valid, the result is **UNPRE-DICTABLE**.

The operands must be values in format *fmt*; if they are not, the result is **UNPREDICTABLE** and the value of the operand FPRs becomes **UNPREDICTABLE**.

The result of MUL.PS is UNPREDICTABLE if the processor is executing in 16 FP registers mode.

Operation:

StoreFPR (fd, fmt, ValueFPR(fs, fmt) \times_{fmt} ValueFPR(ft, fmt))

Exceptions:

Coprocessor Unusable, Reserved Instruction

| Format: MU | JLT rs. | , rt | | | М | IIPS32 |

Format: MULT rs, rt

Purpose: Multiply Word

To multiply 32-bit signed integers

Description: (HI, LO) \leftarrow GPR[rs] \times GPR[rt]

The 32-bit word value in GPR rt is multiplied by the 32-bit value in GPR rs, treating both operands as signed values, to produce a 64-bit result. The low-order 32-bit word of the result is placed into special register LO, and the highorder 32-bit word is splaced into special register Hl.

No arithmetic exception occurs under any circumstances.

Restrictions:

None

Operation:

```
prod \leftarrow GPR[rs]<sub>31..0</sub> × GPR[rt]<sub>31..0</sub>
LO \leftarrow prod_{31..0}
HI \leftarrow prod_{63..32}
```

Exceptions:

None

Programming Notes:

In some processors the integer multiply operation may proceed asynchronously and allow other CPU instructions to execute before it is complete. An attempt to read LO or HI before the results are written interlocks until the results are ready. Asynchronous execution does not affect the program result, but offers an opportunity for performance improvement by scheduling the multiply so that other instructions can execute in parallel.

Programs that require overflow detection must check for it explicitly.

Where the size of the operands are known, software should place the shorter operand in GPR rt. This may reduce the latency of the instruction on those processors which implement data-dependent instruction latencies.

| Format: | NEG.D | mt fd, fs fd, fs S fd, fs | | | | | | PS32 PS32 ase 2 |

Purpose: Floating Point Negate

To negate an FP value

Description: FPR[fd] ← -FPR[fs]

The value in FPR *fs* is negated and placed into FPR *fd*. The value is negated by changing the sign bit value. The operand and result are values in format *fmt*. NEG.PS negates the upper and lower halves of FPR *fs* independently, and ORs together any generated exceptional conditions.

This operation is arithmetic; a NaN operand signals invalid operation.

Restrictions:

The fields *fs* and *fd* must specify FPRs valid for operands of type *fmt*; if they are not valid, the result is **UNPRE-DICTABLE**. The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of NEG.PS is UNPREDICTABLE if the processor is executing in 16 FP registers mode.

Operation:

StoreFPR(fd, fmt, Negate(ValueFPR(fs, fmt)))

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Unimplemented Operation, Invalid Operation

Purpose: Floating Point Negative Multiply Add

To negate a combined multiply-then-add of FP values

Description: $FPR[fd] \leftarrow - ((FPR[fs] \times FPR[ft]) + FPR[fr])$

The value in FPR *fs* is multiplied by the value in FPR *ft* to produce an intermediate product. The intermediate product is rounded according to the current rounding mode in *FCSR*. The value in FPR *fr* is added to the product.

The result sum is calculated to infinite precision, rounded according to the current rounding mode in *FCSR*, negated by changing the sign bit, and placed into FPR *fd*. The operands and result are values in format *fint*. The results and flags are as if separate floating-point multiply and add and negate instructions were executed.

NMADD.PS applies the operation to the upper and lower halves of FPR *fr*, FPR *fs*, and FPR *ft* independently, and ORs together any generated exceptional conditions.

Cause bits are ORed into the Flag bits if no exception is taken.

Restrictions:

The fields *fr*, *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *fmt*; if they are not valid, the result is **UNPREDICTABLE**.

The operands must be values in format *fmt*; if they are not, the result is **UNPREDICTABLE** and the value of the operand FPRs becomes **UNPREDICTABLE**.

The result of NMADD.PS is **UNPREDICTABLE** if the processor is executing in 16 FP registers mode.

Operation:

```
vfr ← ValueFPR(fr, fmt)
vfs ← ValueFPR(fs, fmt)
vft ← ValueFPR(ft, fmt)
StoreFPR(fd, fmt, -(vfr +<sub>fmt</sub> (vfs ×<sub>fmt</sub> vft)))
```

Exceptions:

Purpose: Floating Point Negative Multiply Subtract

To negate a combined multiply-then-subtract of FP values

Description: $FPR[fd] \leftarrow - ((FPR[fs] \times FPR[ft]) - FPR[fr])$

The value in FPR *fs* is multiplied by the value in FPR *ft* to produce an intermediate product. The intermediate product is rounded according to the current rounding mode in *FCSR*. The value in FPR *fr* is subtracted from the product.

The result is calculated to infinite precision, rounded according to the current rounding mode in *FCSR*, negated by changing the sign bit, and placed into FPR *fd*. The operands and result are values in format *fint*. The results and flags are as if separate floating-point multiply and subtract and negate instructions were executed.

NMSUB.PS applies the operation to the upper and lower halves of FPR *fr*, FPR *fs*, and FPR *ft* independently, and ORs together any generated exceptional conditions.

Cause bits are ORed into the Flag bits if no exception is taken.

Restrictions:

The fields *fr*, *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *fmt*; if they are not valid, the result is **UNPREDICTABLE**.

The operands must be values in format *fmt*; if they are not, the result is **UNPREDICTABLE** and the value of the operand FPRs becomes **UNPREDICTABLE**.

The result of NMSUB.PS is **UNPREDICTABLE** if the processor is executing in 16 FP registers mode.

Operation:

```
vfr ← ValueFPR(fr, fmt)
vfs ← ValueFPR(fs, fmt)
vft ← ValueFPR(ft, fmt)
StoreFPR(fd, fmt, -((vfs ×<sub>fmt</sub> vft) -<sub>fmt</sub> vfr))
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

| | 6 | 1 | | 5 | | 5 | | | 5 | | 5 | | | 6 | |

Format: PAUSE

MIPS32 Release 2/MT ASE

Purpose: Wait for the LLBit to clear

Description:

Locks implemented using the LL/SC instructions are a common method of synchronization between threads of control. A typical lock implementation does a load-linked instruction and checks the value returned to determine whether the software lock is set. If it is, the code branches back to retry the load-linked instruction, thereby implementing an active busy-wait sequence. The PAUSE instructions is intended to be placed into the busy-wait sequence to block the instruction stream until such time as the load-linked instruction has a chance to succeed in obtaining the software lock.

The precise behavior of the PAUSE instruction is implementation-dependent, but it usually involves descheduling the instruction stream until the LLBit is zero. In a single-threaded processor, this may be implemented as a short-term WAIT operation which resumes at the next instruction when the LLBit is zero or on some other external event such as an interrupt. On a multi-threaded processor, this may be implemented as a short term YIELD operation which resumes at the next instruction is zero. In either case, it is assumed that the instruction stream which gives up the software lock does so via a write to the lock variable, which causes the processor to clear the LLBit as seen by this thread of execution.

The encoding of the instruction is such that it is backward compatible with all previous implementations of the architecture. The PAUSE instruction can therefore be placed into existing lock sequences and treated as a NOP by the processor, even if the processor does not implement the PAUSE instruction.

Restrictions:

The operation of the processor is **UNPREDICTABLE** if a PAUSE instruction is placed in the delay slot of a branch or a jump.

Operation:

Exceptions:

None

Programming Notes:

The PAUSE instruction is intended to be inserted into the instruction stream after an LL instruction has set the LLBit and found the software lock set. The program may wait forever if a PAUSE instruction is executed and there is no possibility that the LLBit will ever be cleared.

An example use of the PAUSE instruction is included in the following example:

acquire_lock:

| COP1 010001 | fmt 10110 | ft | fs | fd | PLL 101100 |
| 6 | 5 | 5 | 5 | 5 | 6 |

Format: PLL.PS fd, fs, ft

Purpose: Pair Lower Lower

To merge a pair of paired single values with realignment

Description: FPR[fd] ← lower(FPR[fs]) || lower(FPR[ft])

A new paired-single value is formed by catenating the lower single of FPR fs (bits **31..0**) and the lower single of FPR ft (bits **31..0**).

The move is non-arithmetic; it causes no IEEE 754 exceptions.

Restrictions:

The fields *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *PS*. If they are not valid, the result is **UNPRE-DICTABLE**.

The result of this instruction is **UNPREDICTABLE** if the processor is executing in 16 FP registers mode.

Operation:

StoreFPR(fd, PS, ValueFPR(fs, PS)_{31..0} || ValueFPR(ft, PS)_{31..0})

Exceptions:

Coprocessor Unusable, Reserved Instruction

MIPS64, MIPS32 Release 2

| 31 | 26 25 | 21 20 | 16 | 15 0 |
|----------------|-------|-------|------|--------|
| PREF 110011 | bas | se | hint | offset |
| 6 | 5 | 1 | 5 | 16 |
| - | | | | |

Format: PREF hint, offset(base)

Purpose: Prefetch

To move data between memory and cache.

Description: prefetch_memory(GPR[base] + offset)

PREF adds the 16-bit signed *offset* to the contents of GPR *base* to form an effective byte address. The *hint* field supplies information about the way that the data is expected to be used.

PREF enables the processor to take some action, typically causing data to be moved to or from the cache, to improve program performance. The action taken for a specific PREF instruction is both system and context dependent. Any action, including doing nothing, is permitted as long as it does not change architecturally visible state or alter the meaning of a program. Implementations are expected either to do nothing, or to take an action that increases the performance of the program. The PrepareForStore function is unique in that it may modify the architecturally visible state.

PREF does not cause addressing-related exceptions, including TLB exceptions. If the address specified would cause an addressing exception, the exception condition is ignored and no data movement occurs. However even if no data is moved, some action that is not architecturally visible, such as writeback of a dirty cache line, can take place.

It is implementation dependent whether a Bus Error or Cache Error exception is reported if such an error is detected as a byproduct of the action taken by the PREF instruction.

PREF neither generates a memory operation nor modifies the state of a cache line for a location with an *uncached* memory access type, whether this type is specified by the address segment (e.g., kseg1), the programmed cacheability and coherency attribute of a segment (e.g., the use of the K0, KU, or K23 fields in the *Config* register), or the perpage cacheability and coherency attribute provided by the TLB.

If PREF results in a memory operation, the memory access type and cacheability&coherency attribute used for the operation are determined by the memory access type and cacheability&coherency attribute of the effective address, just as it would be if the memory operation had been caused by a load or store to the effective address.

For a cached location, the expected and useful action for the processor is to prefetch a block of data that includes the effective address. The size of the block and the level of the memory hierarchy it is fetched into are implementation specific.

In coherent multiprocessor implementations, if the effective address uses a coherent Cacheability and Coherency Attribute (CCA), then the instruction causes a coherent memory transaction to occur. This means a prefetch issued on one processor can cause data to be evicted from the cache in another processor.

The PREF instruction and the memory transactions which are sourced by the PREF instruction, such as cache refill or cache writeback, obey the ordering and completion rules of the SYNC instruction.

| Value | Name | Data Use and Desired Prefetch Action |
|-------|------|---|
| 0 | load | Use: Prefetched data is expected to be read (not modified). Action: Fetch data as if for a load. |

Table 3.30 Values of *hint* Field for PREF Instruction

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

| 1 | store | Use: Prefetched data is expected to be stored or modified. Action: Fetch data as if for a store. |
|-------|---|---|
| 2-3 | Reserved | Reserved for future use - not available to implementations. |
| 4 | load_streamed | Use: Prefetched data is expected to be read (not modified) but not reused extensively; it "streams" through cache. Action: Fetch data as if for a load and place it in the cache so that it does not displace data prefetched as "retained." |
| 5 | store_streamed | Use: Prefetched data is expected to be stored or modified but not reused extensively; it "streams" through cache. Action: Fetch data as if for a store and place it in the cache so that it does not displace data prefetched as "retained." |
| б | load_retained | Use: Prefetched data is expected to be read (not modified) and reused exten- sively; it should be "retained" in the cache. Action: Fetch data as if for a load and place it in the cache so that it is not displaced by data prefetched as "streamed." |
| 7 | store_retained | Use: Prefetched data is expected to be stored or modified and reused exten- sively; it should be "retained" in the cache. Action: Fetch data as if for a store and place it in the cache so that it is not displaced by data prefetched as "streamed." |
| 8-20 | Reserved | Reserved for future use - not available to implementations. |
| 21-24 | Implementation Dependent | Unassigned by the Architecture - available for implementation-dependent use. |
| 25 | writeback_invalidate (also known as "nudge") | Use: Data is no longer expected to be used. Action: For a writeback cache, schedule a writeback of any dirty data. At the completion of the writeback, mark the state of any cache lines written back as invalid. If the cache line is not dirty, it is implementation dependent whether the state of the cache line is marked invalid or left unchanged. If the cache line is locked, no action is taken. |
| 26-29 | Implementation Dependent | Unassigned by the Architecture - available for implementation-dependent use. |

| 30 | PrepareForStore | Use: Prepare the cache for writing an entire line, without the overhead involved in filling the line from memory. Action: If the reference hits in the cache, no action is taken. If the reference misses in the cache, a line is selected for replacement, any valid and dirty victim is written back to memory, the entire line is filled with zero data, and the state of the line is marked as valid and dirty. Programming Note: Because the cache line is filled with zero data on a cache miss, software must not assume that this action, in and of itself, can be used as a fast bzero-type function. |
|----|--------------------------|--|
| 31 | Implementation Dependent | Unassigned by the Architecture - available for implementation-dependent use. |

Table 3.30 Values of hint Field for PREF Instruction

Restrictions:

None

Operation:

```
vAddr ← GPR[base] + sign_extend(offset)
(pAddr, CCA) ← AddressTranslation(vAddr, DATA, LOAD)
Prefetch(CCA, pAddr, vAddr, DATA, hint)
```

Exceptions:

Bus Error, Cache Error

Prefetch does not take any TLB-related or address-related exceptions under any circumstances.

Programming Notes:

Prefetch cannot move data to or from a mapped location unless the translation for that location is present in the TLB. Locations in memory pages that have not been accessed recently may not have translations in the TLB, so prefetch may not be effective for such locations.

Prefetch does not cause addressing exceptions. A prefetch may be used using an address pointer before the validity of the pointer is determined without worrying about an addressing exception.

It is implementation dependent whether a Bus Error or Cache Error exception is reported if such an error is detected as a byproduct of the action taken by the PREF instruction. Typically, this only occurs in systems which have high-reliability requirements.

Prefetch operations have no effect on cache lines that were previously locked with the CACHE instruction.

Hint field encodings whose function is described as "streamed" or "retained" convey usage intent from software to hardware. Software should not assume that hardware will always prefetch data in an optimal way. If data is to be truly retained, software should use the Cache instruction to lock data into the cache.

| 31 | 26 | 25 21 | 20 16 | 15 | 11 ' | 10 6 | 5 | 0 |
|-----------------|-----|--------------|-------|------|------|------------|-----------------|--------|

| 6 | | 5 | 5 | 5 | | 5 | 6 | |
| Format: PR | EFX | hint, index(| base) | | | | | MIPS64 |

MIPS32 Release 2

Purpose: Prefetch Indexed

To move data between memory and cache.

Description: prefetch_memory[GPR[base] + GPR[index]]

PREFX adds the contents of GPR *index* to the contents of GPR *base* to form an effective byte address. The *hint* field supplies information about the way the data is expected to be used.

The only functional difference between the PREF and PREFX instructions is the addressing mode implemented by the two. Refer to the PREF instruction for all other details, including the encoding of the *hint* field.

Restrictions:

Operation:

```
vAddr ← GPR[base] + GPR[index]
(pAddr, CCA) ← AddressTranslation(vAddr, DATA, LOAD)
Prefetch(CCA, pAddr, vAddr, DATA, hint)
```

Exceptions:

Coprocessor Unusable, Reserved Instruction, Bus Error, Cache Error

Programming Notes:

The PREFX instruction is only available on processors that implement floating point and should never by generated by compilers in situations other than those in which the corresponding load and store indexed floating point instructions are generated.

Also refer to the corresponding section in the PREF instruction description.

Purpose: Pair Upper Upper

To merge a pair of paired single values with realignment

Description: FPR[fd] ← upper(FPR[fs]) || upper(FPR[ft])

A new paired-single value is formed by catenating the upper single of FPR fs (bits 63..32) and the upper single of FPR ft (bits 63..32).

The move is non-arithmetic; it causes no IEEE 754 exceptions.

Restrictions:

The fields fs, ft, and fd must specify FPRs valid for operands of type PS. If they are not valid, the result is UNPRE-DICTABLE.

The result of this instruction is **UNPREDICTABLE** if the processor is executing in 16 FP registers mode.

Operation:

StoreFPR(fd, PS, ValueFPR(fs, PS)_{63..32} || ValueFPR(ft, PS)_{63..32})

Exceptions:

Coprocessor Unusable, Reserved Instruction

MIPS64, MIPS32 Release 2

Format: RDHWR rt,rd

MIPS32 Release 2

RDHWR

Purpose: Read Hardware Register

To move the contents of a hardware register to a general purpose register (GPR) if that operation is enabled by privileged software.

Description: GPR[rt] ← HWR[rd]

If access is allowed to the specified hardware register, the contents of the register specified by *rd* is loaded into general register *rt*. Access control for each register is selected by the bits in the coprocessor 0 *HWREna* register.

The available hardware registers, and the encoding of the *rd* field for each, are shown in Table 3.31.

| Register Number (<i>rd</i> Value) | Mnemonic | | Description | | | | | | | | | |
|--|------------|-----|--|--|--|--|--|--|--|--|--|--|
| 0 | CPUNum | | Number of the CPU on which the program is currently running. This register provides read access to the coprocessor 0 <i>EBase_{CPUNum}</i> field. | | | | | | | | | |
| 1 | SYNCI_Step | nee | address step size to be used with the SYNCI instruction, or zero if no caches eed be synchronized. See that instruction's description for the use of this alue. | | | | | | | | | |
| 2 | CC | | High-resolution cycle counter. This register provides read access to the coprocessor 0 <i>Count</i> Register. | | | | | | | | | |
| | CCRes | | Resolution of the CC register. This value denotes the number of cycles between update of the register. For example: | | | | | | | | | |
| | | | CCRes Value | Meaning | | | | | | | | |
| 3 | | | 1 | CC register increments every CPU cycle | | | | | | | | |
| _ | | | 2 | CC register increments every second CPU cycle | | | | | | | | |
| | | | 3 | CC register increments every third CPU cycle | | | | | | | | |
| | | | | etc. | | | | | | | | |
| 4-28 | | | • | ers are reserved for future architecture use. Access Instruction Exception. | | | | | | | | |
| 29 | ULR | Use | User Local Register. This register provides read access to the coprocessor 0 UserLocal register, if it is implemented. In some operating environments, the UserLocal register is a pointer to a thread-specific storage block. | | | | | | | | | |
| 30-31 | | | | rs are reserved for implementation-dependent use. If nted, access results in a Reserved Instruction Exception. | | | | | | | | |

Table 3.31 RDHWR Register Numbers

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

Restrictions:

In implementations of Release 1 of the Architecture, this instruction resulted in a Reserved Instruction Exception.

Access to the specified hardware register is enabled if Coprocessor 0 is enabled, or if the corresponding bit is set in the *HWREna* register. If access is not allowed or the register is not implemented, a Reserved Instruction Exception is signaled.

Operation:

```
case rd
        0: temp ← EBase<sub>CPUNum</sub>
        1: temp ← SYNCI_StepSize()
        2: temp ← Count
        3: temp ← CountResolution()
        29: temp ← UserLocal
        30: temp ← Implementation-Dependent-Value
        31: temp ← Implementation-Dependent-Value
        otherwise: SignalException(ReservedInstruction)
endcase
GPR[rt] ← temp
```

Exceptions:

Reserved Instruction

| 31 | 26 | 25 2 | 21 2 | 20 16 | 15 1 | 11 | 10 | 0 | |
|-----------------|----|------------------|------|-------|------|----|----|--------------------|--|

| 6 | | 5 | | 5 | 5 | | | 11 | |

Format: RDPGPR rd, rt

Purpose: Read GPR from Previous Shadow Set

To move the contents of a GPR from the previous shadow set to a current GPR.

Description: GPR[rd] ← SGPR[SRSCtl_{PSS}, rt]

The contents of the shadow GPR register specified by SRSCtl_{PSS} (signifying the previous shadow set number) and *rt* (specifying the register number within that set) is moved to the current GPR *rd*.

Restrictions:

In implementations prior to Release 2 of the Architecture, this instruction resulted in a Reserved Instruction Exception.

Operation:

 $GPR[rd] \leftarrow SGPR[SRSCtl_{PSS}, rt]$

Exceptions:

Coprocessor Unusable

Reserved Instruction

MIPS32 Release 2

| 3 | 1 | 26 | 25 | | 21 | 20 | | 16 | 15 | | 11 | 10 | 6 | 5 | | 0 | |
|---|----------------|-------|------|-----|----|----|------------|----|----|----|----|----|---|--------|-----------------|---------|---|
| | COP1 010001 | | | fmt | | | 0 00000 | | | fs | | fd | | | RECIP 010101 | | |
| | 6 | | | 5 | | | 5 | | | 5 | | 5 | | | 6 | | |
| | Format: | RECIE | .fmt | : | | | | | | | | | | | | | |
| | | RECIE | P.S | fd, | fs | | | | | | | | | | 4, MIPS32 | | |
| | | RECIE | P.D | fd, | fs | | | | | | | | | MIPS64 | 4, MIPS32 | Release | 2 |
| | | | | | | | | | | | | | | | | | |

Purpose: Reciprocal Approximation

To approximate the reciprocal of an FP value (quickly)

Description: $FPR[fd] \leftarrow 1.0 / FPR[fs]$

The reciprocal of the value in FPR *fs* is approximated and placed into FPR *fd*. The operand and result are values in format *fmt*.

The numeric accuracy of this operation is implementation dependent; it does not meet the accuracy specified by the IEEE 754 Floating Point standard. The computed result differs from the both the exact result and the IEEE-mandated representation of the exact result by no more than one unit in the least-significant place (ULP).

It is implementation dependent whether the result is affected by the current rounding mode in FCSR.

Restrictions:

The fields *fs* and *fd* must specify FPRs valid for operands of type *fmt*; if they are not valid, the result is **UNPRE-DICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

Operation:

```
StoreFPR(fd, fmt, 1.0 / valueFPR(fs, fmt))
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Inexact, Division-by-zero, Unimplemented Op, Invalid Op, Overflow, Underflow

Purpose: Floating Point Round to Long Fixed Point

To convert an FP value to 64-bit fixed point, rounding to nearest

Description: FPR[fd] \leftarrow convert_and_round(FPR[fs])

The value in FPR *fs*, in format *fmt*, is converted to a value in 64-bit long fixed point format and rounded to nearest/ even (rounding mode 0). The result is placed in FPR *fd*.

When the source value is Infinity, NaN, or rounds to an integer outside the range -2^{63} to 2^{63} -1, the result cannot be represented correctly and an IEEE Invalid Operation condition exists. In this case the Invalid Operation flag is set in the *FCSR*. If the Invalid Operation *Enable* bit is set in the *FCSR*, no result is written to *fd* and an Invalid Operation exception is taken immediately. Otherwise, the default result, 2^{63} -1, is written to *fd*.

Restrictions:

The fields *fs* and *fd*must specify valid FPRs; *fs* for type *fmt* and *fd* for long fixed point; if they are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of this instruction is **UNPREDICTABLE** if the processor is executing in 16 FP registers mode.

Operation:

StoreFPR(fd, L, ConvertFmt(ValueFPR(fs, fmt), fmt, L))

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Inexact, Unimplemented Operation, Invalid Operation, Overflow

Purpose: Floating Point Round to Word Fixed Point

To convert an FP value to 32-bit fixed point, rounding to nearest

Description: FPR[fd] ← convert_and_round(FPR[fs])

The value in FPR *fs*, in format *fint*, is converted to a value in 32-bit word fixed point format rounding to nearest/even (rounding mode 0). The result is placed in FPR *fd*.

When the source value is Infinity, NaN, or rounds to an integer outside the range -2^{31} to 2^{31} -1, the result cannot be represented correctly and an IEEE Invalid Operation condition exists. In this case the Invalid Operation flag is set in the *FCSR*. If the Invalid Operation *Enable* bit is set in the *FCSR*, no result is written to *fd* and an Invalid Operation exception is taken immediately. Otherwise, the default result, 2^{31} -1, is written to *fd*.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs; *fs* for type *fmt* and *fd* for word fixed point; if they are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

Operation:

```
StoreFPR(fd, W, ConvertFmt(ValueFPR(fs, fmt), fmt, W))
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Inexact, Unimplemented Operation, Invalid Operation, Overflow

| 3 | 1 | 26 | 25 | | 21 | 20 | | 16 | 15 | | 1 1 | 10 | | 6 | 5 | | 0 | |

| | | | | | | | | | | | | | | | | | | |

Purpose: Reciprocal Square Root Approximation

To approximate the reciprocal of the square root of an FP value (quickly)

Description: FPR[fd] ← 1.0 / sqrt(FPR[fs])

The reciprocal of the positive square root of the value in FPR *fs* is approximated and placed into FPR *fd*. The operand and result are values in format *fmt*.

The numeric accuracy of this operation is implementation dependent; it does not meet the accuracy specified by the IEEE 754 Floating Point standard. The computed result differs from both the exact result and the IEEE-mandated representation of the exact result by no more than two units in the least-significant place (ULP).

The effect of the current *FCSR* rounding mode on the result is implementation dependent.

Restrictions:

The fields *fs* and *fd* must specify FPRs valid for operands of type *fmt*; if they are not valid, the result is **UNPRE-DICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

Operation:

StoreFPR(fd, fmt, 1.0 / SquareRoot(valueFPR(fs, fmt)))

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Inexact, Division-by-zero, Unimplemented Operation, Invalid Operation, Overflow, Underflow

|----|--------------|-------|-------|--------|
| | SC 111000 | base | rt | offset |
| | 6 | 5 | 5 | 16 |

Format: SC rt, offset(base)

Purpose: Store Conditional Word

To store a word to memory to complete an atomic read-modify-write

Description: if atomic_update then memory[GPR[base] + offset] \leftarrow GPR[rt], GPR[rt] \leftarrow 1 else GPR[rt] \leftarrow 0

The LL and SC instructions provide primitives to implement atomic read-modify-write (RMW) operations for synchronizable memory locations.

The 32-bit word in GPR *rt* is conditionally stored in memory at the location specified by the aligned effective address. The 16-bit signed *offset* is added to the contents of GPR *base* to form an effective address.

The SC completes the RMW sequence begun by the preceding LL instruction executed on the processor. To complete the RMW sequence atomically, the following occur:

- The 32-bit word of GPR *rt* is stored into memory at the location specified by the aligned effective address.
- A 1, indicating success, is written into GPR rt.

Otherwise, memory is not modified and a 0, indicating failure, is written into GPR rt.

If either of the following events occurs between the execution of LL and SC, the SC fails:

- A coherent store is completed by another processor or coherent I/O module into the block of synchronizable physical memory containing the word. The size and alignment of the block is implementation dependent, but it is at least one word and at most the minimum page size.
- An ERET instruction is executed.

If either of the following events occurs between the execution of LL and SC, the SC may succeed or it may fail; the success or failure is not predictable. Portable programs should not cause one of these events.

- A memory access instruction (load, store, or prefetch) is executed on the processor executing the LL/SC.
- The instructions executed starting with the LL and ending with the SC do not lie in a 2048-byte contiguous region of virtual memory. (The region does not have to be aligned, other than the alignment required for instruction words.)

The following conditions must be true or the result of the SC is UNPREDICTABLE:

- Execution of SC must have been preceded by execution of an LL instruction.
- An RMW sequence executed without intervening events that would cause the SC to fail must use the same address in the LL and SC. The address is the same if the virtual address, physical address, and cacheability & coherency attribute are identical.

Atomic RMW is provided only for synchronizable memory locations. A synchronizable memory location is one that is associated with the state and logic necessary to implement the LL/SC semantics. Whether a memory location is synchronizable depends on the processor and system configurations, and on the memory access type used for the

location:

- Uniprocessor atomicity: To provide atomic RMW on a single processor, all accesses to the location must be made with memory access type of either *cached noncoherent* or *cached coherent*. All accesses must be to one or the other access type, and they may not be mixed.
- **MP atomicity:** To provide atomic RMW among multiple processors, all accesses to the location must be made with a memory access type of *cached coherent*.
- **I/O System:** To provide atomic RMW with a coherent I/O system, all accesses to the location must be made with a memory access type of *cached coherent*. If the I/O system does not use coherent memory operations, then atomic RMW cannot be provided with respect to the I/O reads and writes.

Restrictions:

The addressed location must have a memory access type of *cached noncoherent* or *cached coherent*; if it does not, the result is **UNPREDICTABLE**.

The effective address must be naturally-aligned. If either of the 2 least-significant bits of the address is non-zero, an Address Error exception occurs.

Operation:

```
vAddr ← sign_extend(offset) + GPR[base]
if vAddr<sub>1..0</sub> ≠ 0<sup>2</sup> then
   SignalException(AddressError)
endif
(pAddr, CCA) ← AddressTranslation (vAddr, DATA, STORE)
dataword ← GPR[rt]
if LLbit then
   StoreMemory (CCA, WORD, dataword, pAddr, vAddr, DATA)
endif
GPR[rt] ← 0<sup>31</sup> || LLbit
```

Exceptions:

TLB Refill, TLB Invalid, TLB Modified, Address Error, Watch

Programming Notes:

LL and SC are used to atomically update memory locations, as shown below.

```
L1:

LL T1, (T0) # load counter

ADDI T2, T1, 1 # increment

SC T2, (T0) # try to store, checking for atomicity

BEQ T2, 0, L1 # if not atomic (0), try again

NOP # branch-delay slot
```

Exceptions between the LL and SC cause SC to fail, so persistent exceptions must be avoided. Some examples of these are arithmetic operations that trap, system calls, and floating point operations that trap or require software emulation assistance.

LL and SC function on a single processor for *cached noncoherent* memory so that parallel programs can be run on uniprocessor systems that do not support *cached coherent* memory access types.

|--------------------|--------------------|-----|-----------------|
| SPECIAL2 011100 | code - use syscall | | SDBBP 111111 |
| 6 | 20 | 1 | 6 |

Format: SDBBP code

Purpose: Software Debug Breakpoint

To cause a debug breakpoint exception

Description:

This instruction causes a debug exception, passing control to the debug exception handler. If the processor is executing in Debug Mode when the SDBBP instruction is executed, the exception is a Debug Mode Exception, which sets the $Debug_{DExcCode}$ field to the value 0x9 (Bp). The code field can be used for passing information to the debug exception handler, and is retrieved by the debug exception handler only by loading the contents of the memory word containing the instruction, using the DEPC register. The CODE field is not used in any way by the hardware.

Restrictions:

Operation:

```
If Debug<sub>DM</sub> = 0 then
   SignalDebugBreakpointException()
else
   SignalDebugModeBreakpointException()
endif
```

Exceptions:

Format: SEB rd, rt

MIPS32 Release 2

Purpose: Sign-Extend Byte

To sign-extend the least significant byte of GPR rt and store the value into GPR rd.

Description: GPR[rd] ← SignExtend(GPR[rt]_{7..0})

The least significant byte from GPR rt is sign-extended and stored in GPR rd.

Restrictions:

In implementations prior to Release 2 of the architecture, this instruction resulted in a Reserved Instruction Exception.

Operation:

 $GPR[rd] \leftarrow sign_extend(GPR[rt]_{7..0})$

Exceptions:

Reserved Instruction

Programming Notes:

For symmetry with the SEB and SEH instructions, one would expect that there would be ZEB and ZEH instructions that zero-extend the source operand. Similarly, one would expect that the SEW and ZEW instructions would exist to sign- or zero-extend a word to a doubleword. These instructions do not exist because there are functionally-equivalent instructions already in the instruction set. The following table shows the instructions providing the equivalent functions.

| Expected Instruction | Function | Equivalent Instruction |
|----------------------|----------------------|------------------------|
| ZEB rx,ry | Zero-Extend Byte | ANDI rx,ry,0xFF |
| ZEH rx,ry | Zero-Extend Halfword | ANDI rx,ry,0xFFFF |

| 31 | 26 | 25 21 | 20 16 | 15 11 | 10 6 | 5 0 |
|----|--------------------|------------|-------|-------|--------------|-----------------|
| | SPECIAL3 011111 | 0 00000 | rt | rd | SEH 11000 | BSHFL 100000 |
| | 6 | 5 | 5 | 5 | 5 | 6 |

Format: SEH rd, rt

MIPS32 Release 2

Purpose: Sign-Extend Halfword

To sign-extend the least significant halfword of GPR rt and store the value into GPR rd.

Description: GPR[rd] ← SignExtend(GPR[rt]_{15..0})

The least significant halfword from GPR rt is sign-extended and stored in GPR rd.

Restrictions:

In implementations prior to Release 2 of the architecture, this instruction resulted in a Reserved Instruction Exception.

Operation:

 $GPR[rd] \leftarrow sign_extend(GPR[rt]_{15..0})$

Exceptions:

Reserved Instruction

Programming Notes:

The SEH instruction can be used to convert two contiguous halfwords to sign-extended word values in three instructions. For example:

| lw | t0, 0(a1) | /* Read two contiguous halfwords */ | |
|-----|------------|--|---|
| seh | t1, t0 | <pre>/* t1 = lower halfword sign-extended to word *,</pre> | / |
| sra | t0, t0, 16 | <pre>/* t0 = upper halfword sign-extended to word *.</pre> | / |

Zero-extended halfwords can be created by changing the SEH and SRA instructions to ANDI and SRL instructions, respectively.

For symmetry with the SEB and SEH instructions, one would expect that there would be ZEB and ZEH instructions that zero-extend the source operand. Similarly, one would expect that the SEW and ZEW instructions would exist to sign- or zero-extend a word to a doubleword. These instructions do not exist because there are functionally-equivalent instructions already in the instruction set. The following table shows the instructions providing the equivalent functions.

| Expected Instruction | Function | Equivalent Instruction |
|----------------------|----------------------|------------------------|
| ZEB rx,ry | Zero-Extend Byte | ANDI rx,ry,0xFF |
| ZEH rx,ry | Zero-Extend Halfword | ANDI rx,ry,0xFFFF |

| 31 | 26 | 25 21 | 20 16 | 15 | 0 |

| 6 | | 5 | 5 | 16 | _ |
| Format: SI | JTIU rt, | . rs. immed | diate | Ν | AIPS32 |

Format: SLTIU rt, rs, immediate

Purpose: Set on Less Than Immediate Unsigned

To record the result of an unsigned less-than comparison with a constant

Description: GPR[rt] ← (GPR[rs] < immediate)

Compare the contents of GPR rs and the sign-extended 16-bit immediate as unsigned integers and record the Boolean result of the comparison in GPR rt. If GPR rs is less than immediate, the result is 1 (true); otherwise, it is 0 (false).

Because the 16-bit immediate is sign-extended before comparison, the instruction can represent the smallest or largest unsigned numbers. The representable values are at the minimum [0, 32767] or maximum [max unsigned-32767, max_unsigned] end of the unsigned range.

The arithmetic comparison does not cause an Integer Overflow exception.

Restrictions:

None

Operation:

```
if (0 || GPR[rs]) < (0 || sign_extend(immediate)) then
   GPR[rt] \leftarrow 0^{GPRLEN-1} || 1
else
    GPR[rt] \leftarrow 0^{GPRLEN}
endif
```

Format: SLTU rd, rs, rt

Purpose: Set on Less Than Unsigned

To record the result of an unsigned less-than comparison

Description: GPR[rd] ← (GPR[rs] < GPR[rt])

Compare the contents of GPR rs and GPR rt as unsigned integers and record the Boolean result of the comparison in GPR rd. If GPR rs is less than GPR rt, the result is 1 (true); otherwise, it is 0 (false).

The arithmetic comparison does not cause an Integer Overflow exception.

Restrictions:

None

Operation:

```
if (0 || GPR[rs]) < (0 || GPR[rt]) then
   GPR[rd] \leftarrow 0^{GPRLEN-1} || 1
else
   GPR[rd] \leftarrow 0^{GPRLEN}
endif
```

| | | | | | | | | | | | | |

Purpose: Floating Point Square Root

To compute the square root of an FP value

Description: FPR[fd] ← SQRT(FPR[fs])

The square root of the value in FPR *fs* is calculated to infinite precision, rounded according to the current rounding mode in *FCSR*, and placed into FPR *fd*. The operand and result are values in format *fmt*.

If the value in FPR fs corresponds to -0, the result is -0.

Restrictions:

If the value in FPR fs is less than 0, an Invalid Operation condition is raised.

The fields *fs* and *fd* must specify FPRs valid for operands of type *fmt*; if they are not valid, the result is **UNPRE-DICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

Operation:

StoreFPR(fd, fmt, SquareRoot(ValueFPR(fs, fmt)))

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Invalid Operation, Inexact, Unimplemented Operation

| | 6 | 5 | 5 | 5 | 5 | 6 |

Format: SSNOP

Purpose: Superscalar No Operation

Break superscalar issue on a superscalar processor.

Description:

SSNOP is the assembly idiom used to denote superscalar no operation. The actual instruction is interpreted by the hardware as SLL r0, r0, 1.

This instruction alters the instruction issue behavior on a superscalar processor by forcing the SSNOP instruction to single-issue. The processor must then end the current instruction issue between the instruction previous to the SSNOP and the SSNOP. The SSNOP then issues alone in the next issue slot.

On a single-issue processor, this instruction is a NOP that takes an issue slot.

Restrictions:

None

Operation:

None

Exceptions:

None

Programming Notes:

SSNOP is intended for use primarily to allow the programmer control over CP0 hazards by converting instructions into cycles in a superscalar processor. For example, to insert at least two cycles between an MTC0 and an ERET, one would use the following sequence:

mtc0 x,y ssnop ssnop eret

Based on the normal issues rules of the processor, the MTC0 issues in cycle T. Because the SSNOP instructions must issue alone, they may issue no earlier than cycle T+1 and cycle T+2, respectively. Finally, the ERET issues no earlier than cycle T+3. Note that although the instruction after an SSNOP may issue no earlier than the cycle after the SSNOP is issued, that instruction may issue later. This is because other implementation-dependent issue rules may apply that prevent an issue in the next cycle. Processors should not introduce any unnecessary delay in issuing SSNOP instructions.

Format: SUB rd, rs, rt

Purpose: Subtract Word

To subtract 32-bit integers. If overflow occurs, then trap

Description: GPR[rd] ← GPR[rs] - GPR[rt]

The 32-bit word value in GPR rt is subtracted from the 32-bit value in GPR rs to produce a 32-bit result. If the subtraction results in 32-bit 2's complement arithmetic overflow, then the destination register is not modified and an Integer Overflow exception occurs. If it does not overflow, the 32-bit result is placed into GPR rd.

Restrictions:

None

Operation:

```
temp \leftarrow (GPR[rs]_{31} | |GPR[rs]_{31..0}) - (GPR[rt]_{31} | |GPR[rt]_{31..0})
if temp_{32} \neq temp_{31} then
    SignalException(IntegerOverflow)
else
    GPR[rd] \leftarrow temp_{31..0}
endif
```

Exceptions:

Integer Overflow

Programming Notes:

SUBU performs the same arithmetic operation but does not trap on overflow.

| Format: | SUB.D | mt fd, fs, ft fd, fs, ft S fd, fs, f | | | | | | | MIPS32 MIPS32 elease 2 |

Purpose: Floating Point Subtract

To subtract FP values

Description: FPR[fd] ← FPR[fs] - FPR[ft]

The value in FPR *ft* is subtracted from the value in FPR *fs*. The result is calculated to infinite precision, rounded according to the current rounding mode in *FCSR*, and placed into FPR *fd*. The operands and result are values in format *fmt*. SUB.PS subtracts the upper and lower halves of FPR *fs* and FPR *ft* independently, and ORs together any generated exceptional conditions.

Restrictions:

The fields *fs*, *ft*, and *fd* must specify FPRs valid for operands of type *fmt*. If they are not valid, the result is **UNPRE-DICTABLE**.

The operands must be values in format *fmt*; if they are not, the result is **UNPREDICTABLE** and the value of the operand FPRs becomes **UNPREDICTABLE**.

The result of SUB.PS is UNPREDICTABLE if the processor is executing in 16 FP registers mode.

Operation:

StoreFPR (fd, fmt, ValueFPR(fs, fmt) -_{fmt} ValueFPR(ft, fmt))

CPU Exceptions:

Coprocessor Unusable, Reserved Instruction

FPU Exceptions:

Inexact, Overflow, Underflow, Invalid Op, Unimplemented Op

| | 6 | 5 | 5 | 5 | 5 | 6 | - |

Format: SUBU rd, rs, rt

Purpose: Subtract Unsigned Word

To subtract 32-bit integers

Description: GPR[rd] ← GPR[rs] - GPR[rt]

The 32-bit word value in GPR *rt* is subtracted from the 32-bit value in GPR *rs* and the 32-bit arithmetic result is and placed into GPR *rd*.

No integer overflow exception occurs under any circumstances.

Restrictions:

None

Operation:

temp \leftarrow GPR[rs] - GPR[rt] GPR[rd] \leftarrow temp

Exceptions:

None

Programming Notes:

The term "unsigned" in the instruction name is a misnomer; this operation is 32-bit modulo arithmetic that does not trap on overflow. It is appropriate for unsigned arithmetic, such as address arithmetic, or integer arithmetic environments that ignore overflow, such as C language arithmetic.

Format: SUXC1 fs, index(base)

MIPS64, MIPS32 Release 2

Purpose: Store Doubleword Indexed Unaligned from Floating Point

To store a doubleword from an FPR to memory (GPR+GPR addressing) ignoring alignment

Description: memory[(GPR[base] + GPR[index])_{PSIZE-1..3}] ← FPR[fs]

The contents of the 64-bit doubleword in FPR *fs* is stored at the memory location specified by the effective address. The contents of GPR *index* and GPR *base* are added to form the effective address. The effective address is double-word-aligned; EffectiveAddress_{2.0} are ignored.

Restrictions:

The result of this instruction is UNPREDICTABLE if the processor is executing in 16 FP registers mode.

Operation:

```
vAddr \leftarrow (GPR[base]+GPR[index])_{63..3} || 0^{3}
(pAddr, CCA) \leftarrow AddressTranslation(vAddr, DATA, STORE)
datadoubleword \leftarrow ValueFPR(fs, UNINTERPRETED_DOUBLEWORD)

1

The 16-bit signed *offset* is added to the contents of GPR *base* to form an effective address (*EffAddr*). *EffAddr* is the address of the most-significant of 4 consecutive bytes forming a word (W) in memory starting at an arbitrary byte boundary.

A part of *W*, the most-significant 1 to 4 bytes, is in the aligned word containing *EffAddr*. The same number of the most-significant (left) bytes from the word in GPR *rt* are stored into these bytes of *W*.

The following figure illustrates this operation using big-endian byte ordering for 32-bit and 64-bit registers. The 4 consecutive bytes in 2..5 form an unaligned word starting at location 2. A part of *W*, 2 bytes, is located in the aligned word containing the most-significant byte at 2. First, SWL stores the most-significant 2 bytes of the low word from the source register into these 2 bytes in memory. Next, the complementary SWR stores the remainder of the unaligned word.

Purpose: Store Word Right

To store the least-significant part of a word to an unaligned memory address

The 16-bit signed *offset* is added to the contents of GPR *base* to form an effective address (*EffAddr*). *EffAddr* is the address of the least-significant of 4 consecutive bytes forming a word (W) in memory starting at an arbitrary byte boundary.

A part of *W*, the least-significant 1 to 4 bytes, is in the aligned word containing *EffAddr*. The same number of the least-significant (right) bytes from the word in GPR *rt* are stored into these bytes of *W*.

The following figure illustrates this operation using big-endian byte ordering for 32-bit and 64-bit registers. The 4 consecutive bytes in 2..5 form an unaligned word starting at location 2. A part of *W*, 2 bytes, is contained in the aligned word containing the least-significant byte at 5. First, SWR stores the least-significant 2 bytes of the low word from the source register into these 2 bytes in memory. Next, the complementary SWL stores the remainder of the unaligned word.

The bytes stored from the source register to memory depend on both the offset of the effective address within an aligned word—that is, the low 2 bits of the address ($vAddr_{1..0}$)—and the current byte-ordering mode of the processor (big- or little-endian). The following figure shows the bytes stored for every combination of offset and byte-ordering.

| | 6 | 1 | 15 | | 5 | | 6 |
| F | | (stype = 0 imp stype | plied) | | | | MIPS32 MIPS32 |

Purpose: To order loads and stores for shared memory.

Description:

These types of ordering guarantees are available through the SYNC instruction:

- Completion Barriers
- Ordering Barriers

Simple Description for Completion Barrier:

- The barrier affects only *uncached* and *cached coherent* loads and stores.
- The specified memory instructions (loads or stores or both) that occur before the SYNC instruction must be completed before the specified memory instructions after the SYNC are allowed to start.
- Loads are completed when the destination register is written. Stores are completed when the stored value is visible to every other processor in the system.

Detailed Description for Completion Barrier:

- Every synchronizable specified memory instruction (loads or stores or both) that occurs in the instruction stream before the SYNC instruction must be already globally performed before any synchronizable specified memory instructions that occur after the SYNC are allowed to be performed, with respect to any other processor or coherent I/O module.
- The barrier does not guarantee the order in which instruction fetches are performed.
- A stype value of zero will always be defined such that it performs the most complete set of synchronization operations that are defined. This means stype zero always does a completion barrier that affects both loads and stores preceding the SYNC instruction and both loads and stores that are subsequent to the SYNC instruction. Non-zero values of stype may be defined by the architecture or specific implementations to perform synchronization behaviors that are less complete than that of stype zero. If an implementation does not use one of these non-zero values to define a different synchronization behavior, then that non-zero value of stype must act the same as stype zero completion barrier. This allows software written for an implementation with a lighter-weight barrier to work on another implementation which only implements the stype zero completion barrier.
- A completion barrier is required, potentially in conjunction with SSNOP (in Release 1 of the Architecture) or EHB (in Release 2 of the Architecture), to guarantee that memory reference results are visible across operating mode changes. For example, a completion barrier is required on some implementations on entry to and exit from Debug Mode to guarantee that memory effects are handled correctly.

SYNC behavior when the stype field is zero:

• A completion barrier that affects preceding loads and stores and subsequent loads and stores.

Simple Description for Ordering Barrier:

- The barrier affects only *uncached* and *cached coherent* loads and stores.
- The specified memory instructions (loads or stores or both) that occur before the SYNC instruction must always be ordered before the specified memory instructions after the SYNC.
- Memory instructions which are ordered before other memory instructions are processed by the load/store datapath first before the other memory instructions.

Detailed Description for Ordering Barrier:

- Every synchronizable specified memory instruction (loads or stores or both) that occurs in the instruction stream before the SYNC instruction must reach a stage in the load/store datapath after which no instruction re-ordering is possible before any synchronizable specified memory instruction which occurs after the SYNC instruction in the instruction stream reaches the same stage in the load/store datapath.
- If any memory instruction before the SYNC instruction in program order, generates a memory request to the external memory and any memory instruction after the SYNC instruction in program order also generates a memory request to external memory, the memory request belonging to the older instruction must be globally performed before the time the memory request belonging to the younger instruction is globally performed.
- The barrier does not guarantee the order in which instruction fetches are performed.

As compared to the completion barrier, the ordering barrier is a lighter-weight operation as it does not require the specified instructions before the SYNC to be already completed. Instead it only requires that those specified instructions which are subsequent to the SYNC in the instruction stream are never re-ordered for processing ahead of the specified instructions which are before the SYNC in the instruction stream. This potentially reduces how many cycles the barrier instruction must stall before it completes.

The Acquire and Release barrier types are used to minimize the memory orderings that must be maintained and still have software synchronization work.

Implementations that do not use any of the non-zero values of stype to define different barriers, such as ordering barriers, must make those stype values act the same as stype zero.

For the purposes of this description, the CACHE, PREF and PREFX instructions are treated as loads and stores. That is, these instructions and the memory transactions sourced by these instructions obey the ordering and completion rules of the SYNC instruction.

Table 3.32 lists the available completion barrier and ordering barriers behaviors that can be specified using the stype field..

| Code | Name | Older instructions which must reach the load/store ordering point before the SYNC instruction completes. | Younger instructions which must reach the load/store ordering point only after the SYNC instruction completes. | Older instructions which must be globally performed when the SYNC instruction completes | Compliance |
|------------------|-------------------------------|--|---|---|---|
| 0x0 | SYNC or SYNC 0 | Loads, Stores | Loads, Stores | Loads, Stores | Required |

Terms:

Synchronizable: A load or store instruction is *synchronizable* if the load or store occurs to a physical location in shared memory using a virtual location with a memory access type of either *uncached* or *cached coherent*. *Shared memory* is memory that can be accessed by more than one processor or by a coherent I/O system module.

Performed load: A load instruction is *performed* when the value returned by the load has been determined. The result of a load on processor A has been *determined* with respect to processor or coherent I/O module B when a subsequent

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

store to the location by B cannot affect the value returned by the load. The store by B must use the same memory access type as the load.

Performed store: A store instruction is *performed* when the store is observable. A store on processor A is *observable* with respect to processor or coherent I/O module B when a subsequent load of the location by B returns the value written by the store. The load by B must use the same memory access type as the store.

Globally performed load: A load instruction is *globally performed* when it is performed with respect to all processors and coherent I/O modules capable of storing to the location.

Globally performed store: A store instruction is *globally performed* when it is globally observable. It is *globally observable* when it is observable by all processors and I/O modules capable of loading from the location.

Coherent I/O module: A *coherent I/O module* is an Input/Output system component that performs coherent Direct Memory Access (DMA). It reads and writes memory independently as though it were a processor doing loads and stores to locations with a memory access type of *cached coherent*.

Load/Store Datapath: The portion of the processor which handles the load/store data requests coming from the processor pipeline and processes those requests within the cache and memory system hierarchy.

Restrictions:

The effect of SYNC on the global order of loads and stores for memory access types other than *uncached* and *cached coherent* is **UNPREDICTABLE**.

Operation:

SyncOperation(stype)

Exceptions:

None

Programming Notes:

A processor executing load and store instructions observes the order in which loads and stores using the same memory access type occur in the instruction stream; this is known as *program order*.

A *parallel program* has multiple instruction streams that can execute simultaneously on different processors. In multiprocessor (MP) systems, the order in which the effects of loads and stores are observed by other processors—the *global order* of the loads and store—determines the actions necessary to reliably share data in parallel programs.

When all processors observe the effects of loads and stores in program order, the system is *strongly ordered*. On such systems, parallel programs can reliably share data without explicit actions in the programs. For such a system, SYNC has the same effect as a NOP. Executing SYNC on such a system is not necessary, but neither is it an error.

If a multiprocessor system is not strongly ordered, the effects of load and store instructions executed by one processor may be observed out of program order by other processors. On such systems, parallel programs must take explicit actions to reliably share data. At critical points in the program, the effects of loads and stores from an instruction stream must occur in the same order for all processors. SYNC separates the loads and stores executed on the processor into two groups, and the effect of all loads and stores in one group is seen by all processors before the effect of any load or store in the subsequent group. In effect, SYNC causes the system to be strongly ordered for the executing processor at the instant that the SYNC is executed.

Many MIPS-based multiprocessor systems are strongly ordered or have a mode in which they operate as strongly ordered for at least one memory access type. The MIPS architecture also permits implementation of MP systems that are not strongly ordered; SYNC enables the reliable use of shared memory on such systems. A parallel program that does not use SYNC generally does not operate on a system that is not strongly ordered. However, a program that does use SYNC works on both types of systems. (System-specific documentation describes the actions needed to reliably

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

share data in parallel programs for that system.)

The behavior of a load or store using one memory access type is **UNPREDICTABLE** if a load or store was previously made to the same physical location using a different memory access type. The presence of a SYNC between the references does not alter this behavior.

SYNC affects the order in which the effects of load and store instructions appear to all processors; it does not generally affect the physical memory-system ordering or synchronization issues that arise in system programming. The effect of SYNC on implementation-specific aspects of the cached memory system, such as writeback buffers, is not defined.

```
# Processor A (writer)
# Conditions at entry:
# The value 0 has been stored in FLAG and that value is observable by B
                      # change shared DATA value
SW
      R1, DATA
LT
      R2, 1
                       # Perform DATA store before performing FLAG store
SYNC
SW
     R2, FLAG
                       # say that the shared DATA value is valid
   # Processor B (reader)
      LI
           R2, 1
   1: LW
             R1, FLAG # Get FLAG
      BNE
             R2, R1, 1B# if it says that DATA is not valid, poll again
      NOP
      SYNC
                       # FLAG value checked before doing DATA read
      T 'M
             R1, DATA # Read (valid) shared DATA value
```

The code fragments above shows how SYNC can be used to coordinate the use of shared data between separate writer and reader instruction streams in a multiprocessor environment. The FLAG location is used by the instruction streams to determine whether the shared data item DATA is valid. The SYNC executed by processor A forces the store of DATA to be performed globally before the store to FLAG is performed. The SYNC executed by processor B ensures that DATA is not read until after the FLAG value indicates that the shared data is valid.

Software written to use a SYNC instruction with a non-zero stype value, expecting one type of barrier behavior, should only be run on hardware that actually implements the expected barrier behavior for that non-zero stype value or on hardware which implements a superset of the behavior expected by the software for that stype value. If the hardware does not perform the barrier behavior expected by the software, the system may fail.

| 31 | 26 | 25 21 | 20 16 | 15 (| 0 |
|----|------------------|-------|----------------|--------|---|
| | REGIMM 000001 | base | SYNCI 11111 | offset | |
| | 6 | 5 | 5 | 16 | |

Format: SYNCI offset(base)

Purpose: Synchronize Caches to Make Instruction Writes Effective

To synchronize all caches to make instruction writes effective.

Description:

This instruction is used after a new instruction stream is written to make the new instructions effective relative to an instruction fetch, when used in conjunction with the SYNC and JALR.HB, JR.HB, or ERET instructions, as described below. Unlike the CACHE instruction, the SYNCI instruction is available in all operating modes in an implementation of Release 2 of the architecture.

The 16-bit offset is sign-extended and added to the contents of the base register to form an effective address. The effective address is used to address the cache line in all caches which may need to be synchronized with the write of the new instructions. The operation occurs only on the cache line which may contain the effective address. One SYNCI instruction is required for every cache line that was written. See the Programming Notes below.

A TLB Refill and TLB Invalid (both with cause code equal TLBL) exception can occur as a byproduct of this instruction. This instruction never causes TLB Modified exceptions nor TLB Refill exceptions with a cause code of TLBS.

A Cache Error exception may occur as a byproduct of this instruction. For example, if a writeback operation detects a cache or bus error during the processing of the operation, that error is reported via a Cache Error exception. Similarly, a Bus Error Exception may occur if a bus operation invoked by this instruction is terminated in an error.

An Address Error Exception (with cause code equal AdEL) may occur if the effective address references a portion of the kernel address space which would normally result in such an exception. It is implementation dependent whether such an exception does occur.

It is implementation dependent whether a data watch is triggered by a SYNCI instruction whose address matches the Watch register address match conditions. In multiprocessor implementations where instruction caches are not coherently maintained by hardware, the SYNCI instruction may optionally affect all coherent icaches within the system. If the effective address uses a coherent Cacheability and Coherency Attribute (CCA), then the operation may be *globalized*, meaning it is broadcast to all of the coherent instruction caches within the system. If the effective address does not use one of the coherent CCAs, there is no broadcast of the SYNCI operation. If multiple levels of caches are to be affected by one SYNCI instruction, all of the affected cache levels must be processed in the same manner - either all affected cache levels use the globalized behavior.

In multiprocessor implementations where instruction caches are coherently maintained by hardware, the SYNCI instruction should behave as a NOP instruction.

Restrictions:

The operation of the processor is **UNPREDICTABLE** if the effective address references any instruction cache line that contains instructions to be executed between the SYNCI and the subsequent JALR.HB, JR.HB, or ERET instruction required to clear the instruction hazard.

The SYNCI instruction has no effect on cache lines that were previously locked with the CACHE instruction. If correct software operation depends on the state of a locked line, the CACHE instruction must be used to synchronize the caches.

The SYNCI instruction acts on the current processor at a minimum. It is implementation specific whether it affects the caches on other processors in a multi-processor system, except as required to perform the operation on the current

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

MIPS32 Release 2

processor (as might be the case if multiple processors share an L2 or L3 cache).

Full visibility of the new instruction stream requires execution of a subsequent SYNC instruction, followed by a JALR.HB, JR.HB, DERET, or ERET instruction. The operation of the processor is **UNPREDICTABLE** if this sequence is not followed.

Operation:

```
vaddr ← GPR[base] + sign_extend(offset)
SynchronizeCacheLines(vaddr) /* Operate on all caches */
```

Exceptions:

Reserved Instruction Exception (Release 1 implementations only) TLB Refill Exception TLB Invalid Exception Address Error Exception Cache Error Exception Bus Error Exception

Programming Notes:

When the instruction stream is written, the SYNCI instruction should be used in conjunction with other instructions to make the newly-written instructions effective. The following example shows a routine which can be called after the new instruction stream is written to make those changes effective. Note that the SYNCI instruction could be replaced with the corresponding sequence of CACHE instructions (when access to Coprocessor 0 is available), and that the JR.HB instruction could be replaced with JALR.HB, ERET, or DERET instructions, as appropriate. A SYNCI instruction is required between the final SYNCI instruction in the loop and the instruction that clears instruction hazards.

```
/*

| L | 6 | 1 | 19 | 6 | |

Format: TLBP

Purpose: Probe TLB for Matching Entry

To find a matching entry in the TLB.

Description:

The *Index* register is loaded with the address of the TLB entry whose contents match the contents of the *EntryHi* register. If no TLB entry matches, the high-order bit of the *Index* register is set. In Release 1 of the Architecture, it is implementation dependent whether multiple TLB matches are detected on a TLBP. However, implementations are strongly encouraged to report multiple TLB matches only on a TLB write. In Release 2 of the Architecture, multiple TLB matches may only be reported on a TLB write.

Restrictions:

If access to Coprocessor 0 is not enabled, a Coprocessor Unusable Exception is signaled.

Operation:

Exceptions:

Coprocessor Unusable

Machine Check

| 31 | 26 2 | 25 24 | 4 6 | 5 | 0 |
|----------------|------|---------|------------------------------|---------------|---|
| COP0 010000 | C | CO 1 | 0 000 0000 0000 0000 0000 | TLBF 00000 | |
| 6 | | 1 | 19 | 6 | |

Format: TLBR

Purpose: Read Indexed TLB Entry

To read an entry from the TLB.

Description:

The EntryHi, EntryLo0, EntryLo1, and PageMask registers are loaded with the contents of the TLB entry pointed to by the Index register. In Release 1 of the Architecture, it is implementation dependent whether multiple TLB matches are detected on a TLBR. However, implementations are strongly encouraged to report multiple TLB matches only on a TLB write. In Release 2 of the Architecture, multiple TLB matches may only be reported on a TLB write. Note that the value written to the EntryHi, EntryLo0, and EntryLo1 registers may be different from that originally written to the TLB via these registers in that:

- The value returned in the VPN2 field of the *EntryHi* register may havethose bits set to zero corresponding to the one bits in the Mask field of the TLB entry (the least significant bit of VPN2 corresponds to the least significant bit of the Mask field). It is implementation dependent whether these bits are preserved or zeroed after a TLB entry is written and then read.
- The value returned in the PFN field of the *EntryLo0* and *EntryLo1* registers may havethose bits set to zero corresponding to the one bits in the Mask field of the TLB entry (the least significant bit of PFN corresponds to the least significant bit of the Mask field). It is implementation dependent whether these bits are preserved or zeroed after a TLB entry is written and then read.
- The value returned in the G bit in both the *EntryLo0* and *EntryLo1* registers comes from the single G bit in the TLB entry. Recall that this bit was set from the logical AND of the two G bits in *EntryLo0* and *EntryLo1* when the TLB was written.

Restrictions:

The operation is **UNDEFINED** if the contents of the Index register are greater than or equal to the number of TLB entries in the processor.

If access to Coprocessor 0 is not enabled, a Coprocessor Unusable Exception is signaled.

Operation:

```
\begin{split} \mathbf{i} \leftarrow \mathrm{Index} \\ & \text{if i} > (\mathrm{TLBEntries} - 1) \text{ then} \\ & \mathbf{UNDEFINED} \\ & \text{endif} \\ & \text{PageMask}_{\mathrm{Mask}} \leftarrow \mathrm{TLB[i]}_{\mathrm{Mask}} \\ & \text{EntryHi} \leftarrow \\ & (\mathrm{TLB[i]}_{\mathrm{VPN2}} \text{ and not } \mathrm{TLB[i]}_{\mathrm{Mask}}) \mid | \ \# \ \mathrm{Masking \ implementation \ dependent} \\ & \mathbf{0}^5 \mid | \ \mathrm{TLB[i]}_{\mathrm{ASID}} \\ & \text{EntryLo1} \leftarrow \mathbf{0}^2 \mid | \\ & (\mathrm{TLB[i]}_{\mathrm{PFN1}} \text{ and not } \mathrm{TLB[i]}_{\mathrm{Mask}}) \mid | \ \# \ \mathrm{Masking \ mplementation \ dependent} \\ & \mathrm{TLB[i]}_{\mathrm{C1}} \mid | \ \mathrm{TLB[i]}_{\mathrm{D1}} \mid | \ \mathrm{TLB[i]}_{\mathrm{V1}} \mid | \ \mathrm{TLB[i]}_{\mathrm{G}} \\ & \text{EntryLo0} \leftarrow \mathbf{0}^2 \mid | \\ & (\mathrm{TLB[i]}_{\mathrm{PFN0}} \text{ and not } \mathrm{TLB[i]}_{\mathrm{Mask}}) \mid | \ \# \ \mathrm{Masking \ mplementation \ dependent} \end{split}
```

| | 6 | 1 | 19 | | 6 |

Format: TLBWI

Purpose: Write Indexed TLB Entry

To write a TLB entry indexed by the Index register.

Description:

The TLB entry pointed to by the Index register is written from the contents of the *EntryHi*, *EntryLo0*, *EntryLo1*, and *PageMask* registers. It is implementation dependent whether multiple TLB matches are detected on a TLBWI. In such an instance, a Machine Check Exception is signaled. In Release 2 of the Architecture, multiple TLB matches may only be reported on a TLB write. The information written to the TLB entry may be different from that in the *EntryHi*, *EntryLo0*, and *EntryLo1* registers, in that:

- The value written to the VPN2 field of the TLB entry may have those bits set to zero corresponding to the one bits in the Mask field of the *PageMask* register (the least significant bit of VPN2 corresponds to the least significant bit of the Mask field). It is implementation dependent whether these bits are preserved or zeroed during a TLB write.
- The value written to the PFN0 and PFN1 fields of the TLB entry may have those bits set to zero corresponding to the one bits in the Mask field of *PageMask* register (the least significant bit of PFN corresponds to the least significant bit of the Mask field). It is implementation dependent whether these bits are preserved or zeroed during a TLB write.
- The single G bit in the TLB entry is set from the logical AND of the G bits in the *EntryLo0* and *EntryLo1* registers.

Restrictions:

The operation is **UNDEFINED** if the contents of the Index register are greater than or equal to the number of TLB entries in the processor.

If access to Coprocessor 0 is not enabled, a Coprocessor Unusable Exception is signaled.

Operation:

```
\begin{split} & i \leftarrow Index \\ & \text{TLB[i]}_{Mask} \leftarrow \text{PageMask}_{Mask} \\ & \text{TLB[i]}_{VPN2} \leftarrow \text{EntryHi}_{VPN2} \text{ and not PageMask}_{Mask} \ \# \ \text{Implementation dependent} \\ & \text{TLB[i]}_{ASID} \leftarrow \text{EntryHol}_{G} \text{ and EntryLo0}_{G} \\ & \text{TLB[i]}_{G} \leftarrow \text{EntryLo1}_{G} \text{ and EntryLo0}_{G} \\ & \text{TLB[i]}_{PFN1} \leftarrow \text{EntryLo1}_{PFN} \text{ and not PageMask}_{Mask} \ \# \ \text{Implementation dependent} \\ & \text{TLB[i]}_{D1} \leftarrow \text{EntryLo1}_{D} \\ & \text{TLB[i]}_{D1} \leftarrow \text{EntryLo1}_{V} \\ & \text{TLB[i]}_{PFN0} \leftarrow \text{EntryLo0}_{PFN} \text{ and not PageMask}_{Mask} \ \# \ \text{Implementation dependent} \\ & \text{TLB[i]}_{PFN0} \leftarrow \text{EntryLo0}_{D} \\ & \text{TLB[i]}_{D0} \leftarrow \text{EntryLo0}_{D} \\ & \text{TLB[i]}_{D0} \leftarrow \text{EntryLo0}_{D} \\ & \text{TLB[i]}_{D0} \leftarrow \text{EntryLo0}_{D} \\ & \text{TLB[i]}_{V0} \leftarrow \text{EntryLo0}_{V} \end{split}
```

| 6 | 1 | 19 | 6 | |

Format: TLBWR

Purpose: Write Random TLB Entry

To write a TLB entry indexed by the Random register.

Description:

The TLB entry pointed to by the *Random* register is written from the contents of the *EntryHi*, *EntryLo0*, *EntryLo1*, and *PageMask* registers. It is implementation dependent whether multiple TLB matches are detected on a TLBWR. In such an instance, a Machine Check Exception is signaled. In Release 2 of the Architecture, multiple TLB matches may only be reported on a TLB write. The information written to the TLB entry may be different from that in the *EntryHi*, *EntryLo0*, and *EntryLo1* registers, in that:

- The value written to the VPN2 field of the TLB entry may have those bits set to zero corresponding to the one bits in the Mask field of the *PageMask* register (the least significant bit of VPN2 corresponds to the least significant bit of the Mask field). It is implementation dependent whether these bits are preserved or zeroed during a TLB write.
- The value written to the PFN0 and PFN1 fields of the TLB entry may have those bits set to zero corresponding to the one bits in the Mask field of *PageMask* register (the least significant bit of PFN corresponds to the least significant bit of the Mask field). It is implementation dependent whether these bits are preserved or zeroed during a TLB write.
- The single G bit in the TLB entry is set from the logical AND of the G bits in the *EntryLo0* and *EntryLo1* registers.

Restrictions:

If access to Coprocessor 0 is not enabled, a Coprocessor Unusable Exception is signaled.

Operation:

```
\begin{split} & i \leftarrow \text{Random} \\ & \text{TLB[i]}_{Mask} \leftarrow \text{PageMask}_{Mask} \\ & \text{TLB[i]}_{VPN2} \leftarrow \text{EntryHi}_{VPN2} \text{ and not PageMask}_{Mask} \ \# \ \text{Implementation dependent} \\ & \text{TLB[i]}_{ASID} \leftarrow \text{EntryHo}_{G} \text{ and EntryLo0}_{G} \\ & \text{TLB[i]}_{C1} \leftarrow \text{EntryLo1}_{PFN} \text{ and not PageMask}_{Mask} \ \# \ \text{Implementation dependent} \\ & \text{TLB[i]}_{C1} \leftarrow \text{EntryLo1}_{C} \\ & \text{TLB[i]}_{D1} \leftarrow \text{EntryLo1}_{D} \\ & \text{TLB[i]}_{V1} \leftarrow \text{EntryLo1}_{V} \\ & \text{TLB[i]}_{PFN0} \leftarrow \text{EntryLo0}_{PFN} \text{ and not PageMask}_{Mask} \ \# \ \text{Implementation dependent} \\ & \text{TLB[i]}_{D1} \leftarrow \text{EntryLo1}_{V} \\ & \text{TLB[i]}_{PFN0} \leftarrow \text{EntryLo0}_{PFN} \text{ and not PageMask}_{Mask} \ \# \ \text{Implementation dependent} \\ & \text{TLB[i]}_{D0} \leftarrow \text{EntryLo0}_{C} \\ & \text{TLB[i]}_{D0} \leftarrow \text{EntryLo0}_{D} \\ & \text{TLB[i]}_{V0} \leftarrow \text{EntryLo0}_{V} \\ \end{aligned}

| 6 | 5 | | 5 | 1 | 5 | 5 | 6 | |
| Format: TRUNC.L.fmt TRUNC.L.S fd, fs MIPS64, MIPS3 TRUNC.L.D fd, fs MIPS64, MIPS3 Purpose: Floating Point Truncate to Long Fixed Point | | | | | | | | |

To convert an FP value to 64-bit fixed point, rounding toward zero

Description: FPR[fd] ← convert_and_round(FPR[fs])

The value in FPR *fs*, in format *fmt*, is converted to a value in 64-bit long fixed point format and rounded toward zero (rounding mode 1). The result is placed in FPR *fd*.

When the source value is Infinity, NaN, or rounds to an integer outside the range -2^{63} to 2^{63} -1, the result cannot be represented correctly and an IEEE Invalid Operation condition exists. In this case the Invalid Operation flag is set in the *FCSR*. If the Invalid Operation *Enable* bit is set in the *FCSR*, no result is written to *fd* and an Invalid Operation exception is taken immediately. Otherwise, the default result, 2^{63} -1, is written to *fd*.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs; *fs* for type *fmt* and *fd* for long fixed point; if they are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fint*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

The result of this instruction is **UNPREDICTABLE** if the processor is executing in 16 FP registers mode.

Operation:

StoreFPR(fd, L, ConvertFmt(ValueFPR(fs, fmt), fmt, L))

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

To convert an FP value to 32-bit fixed point, rounding toward zero

Description: FPR[fd] ← convert_and_round(FPR[fs])

The value in FPR fs, in format fmt, is converted to a value in 32-bit word fixed point format using rounding toward zero (rounding mode 1). The result is placed in FPR fd.

When the source value is Infinity, NaN, or rounds to an integer outside the range -2^{31} to 2^{31} -1, the result cannot be represented correctly and an IEEE Invalid Operation condition exists. In this case the Invalid Operation flag is set in the *FCSR*. If the Invalid Operation *Enable* bit is set in the *FCSR*, no result is written to *fd* and an Invalid Operation exception is taken immediately. Otherwise, the default result, 2^{31} -1, is written to *fd*.

Restrictions:

The fields *fs* and *fd* must specify valid FPRs; *fs* for type *fmt* and *fd* for word fixed point; if they are not valid, the result is **UNPREDICTABLE**.

The operand must be a value in format *fmt*; if it is not, the result is **UNPREDICTABLE** and the value of the operand FPR becomes **UNPREDICTABLE**.

Operation:

```
StoreFPR(fd, W, ConvertFmt(ValueFPR(fs, fmt), fmt, W))
```

Exceptions:

Coprocessor Unusable, Reserved Instruction

Floating Point Exceptions:

Inexact, Invalid Operation, Overflow, Unimplemented Operation

MIPS32

| 31 | : | 26 25 | 24 6 | 5 | 0 |
|----|----------------|---------|-------------------------------|---|----------------|
| | COP0 010000 | CO 1 | Implementation-dependent code | | WAIT 100000 |
| | 6 | 1 | 19 | | 6 |

Format: WAIT

Purpose: Enter Standby Mode

Wait for Event

Description:

The WAIT instruction performs an implementation-dependent operation, usually involving a lower power mode. Software may use bits 24:6 of the instruction to communicate additional information to the processor, and the processor may use this information as control for the lower power mode. A value of zero for bits 24:6 is the default and must be valid in all implementations.

The WAIT instruction is typically implemented by stalling the pipeline at the completion of the instruction and entering a lower power mode. The pipeline is restarted when an external event, such as an interrupt or external request occurs, and execution continues with the instruction following the WAIT instruction. It is implementation-dependent whether the pipeline restarts when a non-enabled interrupt is requested. In this case, software must poll for the cause of the restart. The assertion of any reset or NMI must restart the pipeline and the corresponding exception must be taken.

If the pipeline restarts as the result of an enabled interrupt, that interrupt is taken between the WAIT instruction and the following instruction (EPC for the interrupt points at the instruction following the WAIT instruction).

Restrictions:

The operation of the processor is **UNDEFINED** if a WAIT instruction is placed in the delay slot of a branch or a jump.

If access to Coprocessor 0 is not enabled, a Coprocessor Unusable Exception is signaled.

Operation:

```
I: Enter implementation dependent lower power mode
I+1:/* Potential interrupt taken here */
```

Exceptions:

Coprocessor Unusable Exception

| | 6 | 5 | 5 | 5 | 11 |

Format: WRPGPR rd, rt

Purpose: Write to GPR in Previous Shadow Set

To move the contents of a current GPR to a GPR in the previous shadow set.

Description: SGPR[SRSCtl_{PSS}, rd] ← GPR[rt]

The contents of the current GPR rt is moved to the shadow GPR register specified by SRSCtl_{PSS} (signifying the previous shadow set number) and rd (specifying the register number within that set).

Restrictions:

In implementations prior to Release 2 of the Architecture, this instruction resulted in a Reserved Instruction Exception.

Operation:

 $SGPR[SRSCtl_{PSS}, rd] \leftarrow GPR[rt]$

Exceptions:

Coprocessor Unusable

Reserved Instruction

MIPS32 Release 2

| 31 | 2 | 26 | 25 21 | 20 | 16 | 15 | 11 | 10 | 6 | 5 | | 0 |
|----|--------------------|----|------------|----|----|----|----|---------------|---|---|--------------|---|
| | SPECIAL3 011111 | | 0 00000 | rt | | rd | | WSBH 00010 | | | 5HFL 0000 | |
| | 6 | | 5 | 5 | | 5 | | 5 | | | 6 | |

Format: WSBH rd, rt

Purpose: Word Swap Bytes Within Halfwords

To swap the bytes within each halfword of GPR *rt* and store the value into GPR *rd*.

Description: GPR[rd] ← SwapBytesWithinHalfwords(GPR[rt])

Within each halfword of GPR rt the bytes are swapped, and stored in GPR rd.

Restrictions:

In implementations prior to Release 2 of the architecture, this instruction resulted in a Reserved Instruction Exception.

Operation:

 $\mathsf{GPR}[\mathsf{rd}] \leftarrow \mathsf{GPR}[\mathsf{r}]_{23..16} || \mathsf{GPR}[\mathsf{r}]_{31..24} || \mathsf{GPR}[\mathsf{r}]_{7..0} || \mathsf{GPR}[\mathsf{r}]_{15..8}$

Exceptions:

Reserved Instruction

Programming Notes:

The WSBH instruction can be used to convert halfword and word data of one endianness to another endianness. The endianness of a word value can be converted using the following sequence:

| lw | t0, 0(a1) | /* Read word value */ |
|------|------------|---|
| wsbh | t0, t0 | /* Convert endiannes of the halfwords */ |
| rotr | t0, t0, 16 | /* Swap the halfwords within the words */ |

Combined with SEH and SRA, two contiguous halfwords can be loaded from memory, have their endianness converted, and be sign-extended into two word values in four instructions. For example:

| lw | t0, 0(a1) | /* Read two contiguous halfwords */ |
|------|------------|--|
| wsbh | t0, t0 | /* Convert endiannes of the halfwords */ |
| seh | t1, t0 | <pre>/* t1 = lower halfword sign-extended to word */</pre> |
| sra | t0, t0, 16 | <pre>/* t0 = upper halfword sign-extended to word */</pre> |

Zero-extended words can be created by changing the SEH and SRA instructions to ANDI and SRL instructions, respectively.

Description: GPR[rt] ← GPR[rs] XOR immediate

Combine the contents of GPR *rs* and the 16-bit zero-extended *immediate* in a bitwise logical Exclusive OR operation and place the result into GPR *rt*.

Restrictions:

None

Operation:

GPR[rt] ← GPR[rs] xor zero_extend(immediate)

Exceptions:

None

Instruction Bit Encodings

A.1 Instruction Encodings and Instruction Classes

Instruction encodings are presented in this section; field names are printed here and throughout the book in *italics*.

When encoding an instruction, the primary *opcode* field is encoded first. Most *opcode* values completely specify an instruction that has an *immediate* value or offset.

Opcode values that do not specify an instruction instead specify an instruction class. Instructions within a class are further specified by values in other fields. For instance, *opcode* REGIMM specifies the *immediate* instruction class, which includes conditional branch and trap *immediate* instructions.

A.2 Instruction Bit Encoding Tables

This section provides various bit encoding tables for the instructions of the MIPS32® ISA.

Figure A.1 shows a sample encoding table and the instruction *opcode* field this table encodes. Bits 31..29 of the *opcode* field are listed in the leftmost columns of the table. Bits 28..26 of the *opcode* field are listed along the topmost rows of the table. Both decimal and binary values are given, with the first three bits designating the row, and the last three bits designating the column.

An instruction's encoding is found at the intersection of a row (bits 31..29) and column (bits 28..26) value. For instance, the *opcode* value for the instruction labelled EX1 is 33 (decimal, row and column), or 011011 (binary). Similarly, the *opcode* value for EX2 is 64 (decimal), or 110100 (binary).

Figure A.1 Sample Bit Encoding Table

Tables A.2 through A.20 describe the encoding used for the MIPS32 ISA. Table A.1 describes the meaning of the symbols used in the tables.

| Symbol | Meaning |
|--------|---|
| * | Operation or field codes marked with this symbol are reserved for future use. Executing such an instruction must cause a Reserved Instruction Exception. |
| δ | (Also <i>italic</i> field name.) Operation or field codes marked with this symbol denotes a field class. The instruction word must be further decoded by examining additional tables that show values for another instruction field. |
| β | Operation or field codes marked with this symbol represent a valid encoding for a higher-order MIPS ISA level or a new revision of the Architecture. Executing such an instruction must cause a Reserved Instruction Exception. |
| V | Operation or field codes marked with this symbol represent instructions which were only legal if 64-bit operations were enabled on implementations of Release 1 of the Architecture. In Release 2 of the architecture, operation or field codes marked with this symbol represent instructions which are legal if 64-bit floating point operations are enabled. In other cases, executing such an instruction must cause a Reserved Instruction Exception (non-coprocessor encodings or coprocessor instruction encodings for a coprocessor to which access is allowed) or a Coprocessor Unusable Exception (coprocessor instruction encodings for a coprocessor to which access is not allowed). |

Table A.1 Symbols Used in the Instruction Encoding Tables

| Symbol | Meaning |
|--------|--|
| θ | Operation or field codes marked with this symbol are available to licensed MIPS partners. To avoid multiple conflicting instruction definitions, MIPS Technologies will assist the partner in selecting appropriate encodings if requested by the partner. The partner is not required to consult with MIPS Technologies when one of these encodings is used. If no instruction is encoded with this value, executing such an instruction must cause a Reserved Instruction Exception (<i>SPECIAL2</i> encodings or coprocessor instruction encodings for a coprocessor to which access is allowed) or a Coprocessor Unusable Exception (coprocessor instruction encodings for a coprocessor to which access is not allowed). |
| σ | Field codes marked with this symbol represent an EJTAG support instruction and implementa- tion of this encoding is optional for each implementation. If the encoding is not implemented, executing such an instruction must cause a Reserved Instruction Exception. If the encoding is implemented, it must match the instruction encoding as shown in the table. |
| ε | Operation or field codes marked with this symbol are reserved for MIPS Application Specific Extensions. If the ASE is not implemented, executing such an instruction must cause a Reserved Instruction Exception. |
| φ | Operation or field codes marked with this symbol are obsolete and will be removed from a future revision of the MIPS32 ISA. Software should avoid using these operation or field codes. |
| • | Operation or field codes marked with this symbol are valid for Release 2 implementations of the architecture. Executing such an instruction in a Release 1 implementation must cause a Reserved Instruction Exception. |

Table A.2 MIPS32 Encoding of the Opcode Field

1. In Release 1 of the Architecture, the COP1X opcode was called COP3, and was available as another user-available coprocessor. In Release 2 of the Architecture, a full 64-bit floating point unit is available with 32-bit CPUs, and the COP1X opcode is reserved for that purpose on all Release 2 CPUs. 32-bit implementations of Release 1 of the architecture are strongly discouraged from using this opcode for a user-available coprocessor as doing so will limit the potential for an upgrade path to a 64-bit floating point unit.

2. Release 2 of the Architecture added the SPECIAL3 opcode. Implementations of Release 1 of the Architecture signaled a Reserved Instruction Exception for this opcode.

| fur | nction | bits 20 | | | | | | | |

1. COP1X instructions are legal only if 64-bit floating point operations are enabled.

A.3 Floating Point Unit Instruction Format Encodings

Instruction format encodings for the floating point unit are presented in this section. This information is a tabular presentation of the encodings described in tables Table A.13 and Table A.20 above.

| | field 521 of opcode) | <i>fmt3</i> field (bits 20 of COP1X opcode) | | | | | |
|---------|----------------------------|---|-----|---|--------|-----------|-------------------|
| Decimal | Hex | Decimal | Hex | Mnemonic | Name | Bit Width | Data Type |
| 015 | 000F | | | Used to encode Coprocessor 1 interface instructions (MFC1, CTC1, etc.). Not used for format encoding. | | | |
| 16 | 10 | 0 | 0 | S | Single | 32 | Floating Point |
| 17 | 11 | 1 | 1 | D | Double | 64 | Floating Point |
| 1819 | 1213 | 23 | 23 | Reserved for future use by the architecture. | | | |
| 20 | 14 | 4 | 4 | W | Word | 32 | Fixed Point |

 Table A.21 Floating Point Unit Instruction Format Encodings

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

| <i>fmt</i> field (bits 2521 of COP1 opcode) | | <i>fmt3</i> field (bits 20 of COP1X opcode) | | | | | |
|---|------|---|-----|--|--------------------|-----------|-------------------|
| Decimal | Hex | Decimal | Hex | Mnemonic | Name | Bit Width | Data Type |
| 21 | 15 | 5 | 5 | L | Long | 64 | Fixed Point |
| 22 | 16 | 6 | 6 | PS | Paired Sin- gle | 2 × 32 | Floating Point |
| 23 | 17 | 7 | 7 | Reserved for future use by the architecture. | | | |
| 2431 | 181F | | | Reserved for future use by the architecture. Not available for <i>fmt3</i> encoding. | | | |

Table A.21 Floating Point Unit Instruction Format Encodings

Revision History

In the left hand page margins of this document you may find vertical change bars to note the location of significant changes to this document since its last release. Significant changes are defined as those which you should take note of as you use the MIPS IP. Changes to correct grammar, spelling errors or similar may or may not be noted with change bars. Change bars will be removed for changes which are more than one revision old.

Please note: Limitations on the authoring tools make it difficult to place change bars on changes to figures. Change bars on figure titles are used to denote a potential change in the figure itself.

| Revision | Date | Description |
|----------|-------------------|---|
| 0.90 | November 1, 2000 | Internal review copy of reorganized and updated architecture documentation. |
| 0.91 | November 15, 2000 | Internal review copy of reorganized and updated architecture documentation. |
| 0.92 | December 15, 2000 | Changes in this revision: Correct sign in description of MSUBU. Update JR and JALR instructions to reflect the changes required by MIPS16. |
| 0.95 | March 12, 2001 | Update for second external review release |
| 1.00 | August 29, 2002 | Update based on all review feedback: Add missing optional select field syntax in mtc0/mfc0 instruction descriptions. Correct the PREF instruction description to acknowledge that the Prepare-ForStore function does, in fact, modify architectural state. To provide additional flexibility for Coprocessor 2 implementations, extend the <i>sel</i> field for DMFC0, DMTC0, MFC0, and MTC0 to be 8 bits. Update the PREF instruction to note that it may not update the state of a locked cache line. Remove obviously incorrect documentation in DIV and DIVU with regard to putting smaller numbers in register <i>rt</i>. Fix the description for MFC2 to reflect data movement from the coprocessor 2 register to the GPR, rather than the other way around. Correct the pseudo code for LDC1, LDC2, SDC1, and SDC2 for a MIPS32 implementation to show the required word swapping. Indicate that the operation of the CACHE instruction is UNPREDICTABLE if the cache line containing the instruction is the target of an invalidate or writeback invalidate. Indicate that an Index Load Tag or Index Store Tag operation of the CACHE instruction must not cause a cache error exception. Make the entire right half of the MFC2, MTC2, CFC2, CTC2, DMFC2, and DMTC2 instructions implementation dependent, thereby acknowledging that these fields can be used in any way by a Coprocessor 2 implementation. Clean up the definitions of LL, SC, LLD, and SCD. Add a warning that software should not use non-zero values of the stype field of the SYNC instruction. |

MIPS® Architecture For Programmers Volume II-A: The MIPS32® Instruction Set, Revision 3.00

| Revision | Date | Description |
|----------|-------------------|--|
| 1.90 | September 1, 2002 | Merge the MIPS Architecture Release 2 changes in for the first release of a Release 2 processor. Changes in this revision include: All new Release 2 instructions have been included: DI, EHB, EI, EXT, INS, JALR.HB, JR.HB, MFHC1, MFHC2, MTHC1, MTHC2, RDHWR, RDPGPR, ROTR, ROTRV, SEB, SEH, SYNCI, WRPGPR, WSBH. The following instruction definitions changed to reflect Release 2 of the Architecture: DERET, ERET, JAL, JALR, JR, SRL, SRLV With support for 64-bit FPUs on 32-bit CPUs in Release 2, all floating point instructions that were previously implemented by MIPS64 processors have been modified to reflect support on either MIPS32 or MIPS64 processors in Release 2. All pseudo-code functions have been updated, and the Are64bitFPOperationsEnabled function was added. Update the instruction encoding tables for Release 2. |
| 2.00 | June 9, 2003 | Continue with updates to merge Release 2 changes into the document. Changes in this revision include: Correct the target GPR (from rd to rt) in the SLTI and SLTIU instructions. This appears to be a day-one bug. Correct CPR number, and missing data movement in the pseudocode for the MTC0 instruction. Add note to indicate that the CACHE instruction does not take Address Error Exceptions due to mis-aligned effective addresses. Update SRL, ROTR, SRLV, ROTRV, DSRL, DROTR, DSRLV, DROTRV, DSRL32, and DROTR32 instructions to reflect a 1-bit, rather than a 4-bit decode of shift vs. rotate function. Add note to the PREF and PREFX instruction indicating that they may cause Bus Error and Cache Error exceptions, although this is typically limited to systems with high-reliability requirements. Update the SYNCI instruction to indicate that it should not modify the state of a locked cache line. Establish specific rules for when multiple TLB matches can be reported (on writes only). This makes software handling easier. |
| 2.50 | July 1, 2005 | Changes in this revision: Correct figure label in LWR instruction (it was incorrectly specified as LWL). Update all files to FrameMaker 7.1. Include support for implementation-dependent hardware registers via RDHWR. Indicate that it is implementation-dependent whether prefetch instructions cause EJTAG data breakpoint exceptions on an address match, and suggest that the preferred implementation is not to cause an exception. Correct the MIPS32 pseudocode for the LDC1, LDXC1, LUXC1, SDC1, SDXC1, and SUXC1 instructions to reflect the Release 2 ability to have a 64-bit FPU on a 32-bit CPU. The correction simplifies the code by using the ValueFPR and StoreFPR functions, which correctly implement the Release 2 access to the FPRs. Add an explicit recommendation that all cache operations that require an index be done by converting the index to a kseg0 address before performing the cache operation. Expand on restrictions on the PREF instruction in cases where the effective address has an uncached coherency attribute. |

| Revision | Date | Description |
|----------|-----------------|---|
| 2.60 | June 25, 2008 | Changes in this revision: Applied the new B0.01 template. Update RDHWR description with the UserLocal register. added PAUSE instruction Ordering SYNCs CMP behavior of CACHE, PREF*, SYNCI CVT.S.PL, CVT.S.PU are non-arithmetic (no exceptions) *MADD.fmt & *MSUB.fmt are non-fused. various typos fixed |
| 2.61 | July 10, 2008 | Revision History file was incorrectly copied from Volume III. Removed index conditional text from PAUSE instruction description. SYNC instruction - added additional format "SYNC stype" |
| 2.62 | January 2, 2009 | LWC1, LWXC1 - added statement that upper word in 64bit registers are UNDEFINED. CVT.S.PL and CVT.S.PU descriptions were still incorrectly listing IEEE exceptions. Typo in CFC1 Description. CCRes is accessed through \$3 for RDHWR, not \$4. |
| 3.00 | March 25, 2010 | JALX instruction description added. Sub-setting rules updated for JALX. |
